# 1 Introduction

**BAWT** is a configurable framework written in **Tcl** for building **C/C++** based software libraries from source code without user interaction. Its main usage is for the **Windows** operating system, where heterogeneous build environments and compilers are needed (or wanted) to build these libraries:

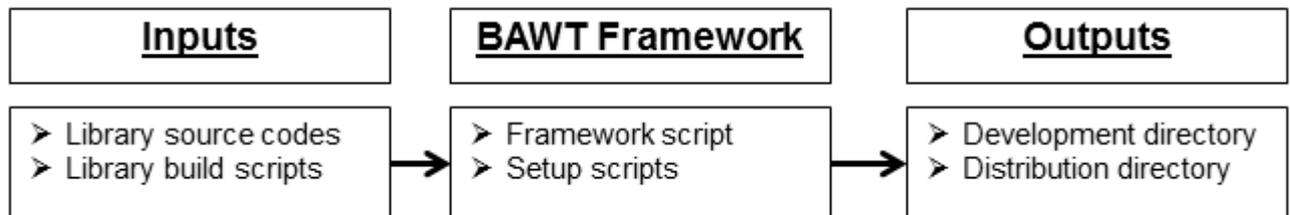

- `configure/make` (via MSYS / MinGW)
- `nmake`
- `CMake`
- Visual Studio Solutions
  
- `gcc` (via MSYS / MinGW)
- Visual Studio

Due to the portable nature of **Tcl** the framework can be used on **Linux** and **Darwin** as well using the `configure/make/gcc` build chain.

The libraries currently supported by **BAWT** are mainly from the **Tcl** and **OpenSceneGraph** ecosystems. Therefore the framework also supports creating installation executables on Windows (based on **InnoSetup**) for these two domains.

See chapter [8 Supported Libraries](#) for a list of currently supported libraries.

The framework itself is just one plain Tcl file *Bawt.tcl*, which reads a *Setup* file containing all the libraries to be built. Each library must have an accompanying *Build* file, which contains the details on how to extract, configure, compile and distribute the library. The library itself is stored as one or more zipped source code files, which may contain different versions of the library. The generated shared or static libraries, programs and header files are finally copied into ready-to-use directory structures for use by developers or for software distribution.

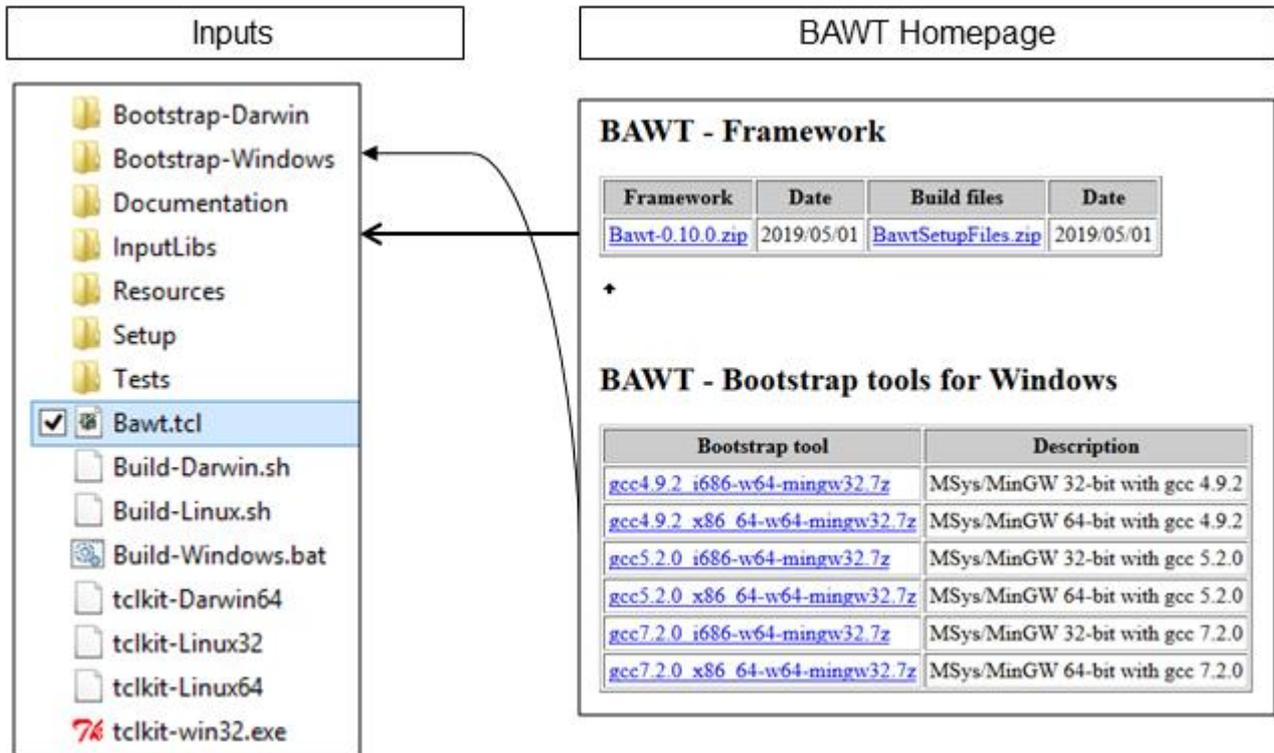

The **BAWT** framework (including *Bootstrap* and *Setup* files) as well as the needed MSYS/MinGW files (if running on Windows) must be downloaded manually. You do not need to have Tcl installed to execute the framework. **BAWT** comes with Tclkits (single-file Tcl interpreter) for Windows, Linux and Darwin. The library *Build* and source files can be downloaded automatically on demand.

The **BAWT** homepage is at <http://www.bawt.tcl3d.org>.

**BAWT** is copyrighted by Paul Obermeier and distributed under the [3-clause BSD license](#).

## 2 Installation and Usage Examples

This chapter explains the installation of the **BAWT** framework and gives first simple use cases. **BAWT** related downloads are available at <http://www.bawt.tcl3d.org/download.html>.

### 2.1 Installation on Windows

#### Prerequisites:

- None for building libraries supporting MSYS / MinGW.
- Otherwise Visual Studio or Visual Studio Express.
  - Visual Studio Versions 2008, 2010, 2012, 2013, 2015, 2017, 2019 are currently supported.
  - If Visual Studio is not installed in the standard location, you have to adapt procedure *GetVcvarsProg* in file *Bawt.tcl*.

#### Downloads:

- **BAWT** framework *Bawt-1.2.0.zip*
- MSys/MinGW distribution(s)

#### Installation:

- Extract **BAWT** framework *Bawt-1.2.0.zip* in a folder of choice, ex. *C:\Bawt*
- Copy MSys/MinGW distribution(s) into *C:\Bawt\Bawt-1.2.0\Bootstrap-Windows*
- Open command shell window and go into folder *C:\Bawt\Bawt-1.2.0*

#### Usage examples:

- Create basic Tcl packages for 32-bit (using MSYS / MinGW):
 

```
> Build-Windows.bat x86 gcc Setup\Tcl_Basic.bawt update
```
- Create basic Tcl packages for 64-bit (using MSYS / MinGW):

```
> Build-Windows.bat x64 gcc Setup\Tcl_Basic.bawt update
```

- Create extended Tcl packages including InnoSetup installation executable for 64-bit (using Visual Studio 2013 to build some additional Tcl packages like *Mpexpr* and *tkdnd*):

```
> Build-Windows.bat x64 vs2013 Setup\Tcl_Distribution.bawt update
```

## 2.2 Installation on Linux

### Prerequisites:

- Required: C/C++ development package, curl, p7zip
- Optional: Dependent on the libraries. See below for distribution specific examples.

### Downloads:

- **BAWT** framework *Bawt-1.2.0.zip*

### Installation:

- Extract **BAWT** framework *Bawt-1.2.0.zip* in a folder of choice, ex. */opt/Bawt*
- Open shell (Terminal window), go into created folder */opt/Bawt Bawt-1.2.0* and execute:

```
> chmod u+x Build*.sh
```

```
> chmod u+x tclkit*
```

### Usage examples:

- Create basic Tcl packages for 32-bit:

```
> ./Build-Linux.sh x86 Setup/Tcl_Basic.bawt update
```

- Create extended Tcl packages including simple shell based installation script for 64-bit:

```
> ./Build-Linux.sh x64 Setup/Tcl_Distribution.bawt update
```

### Distribution specific prerequisites:

See chapter [3.2 Setup Files](#) for a list of available Setup files and the dependencies between Setup files. If you want to build ex. *Tcl\_Extended.bawt*, you must not only install the prerequisites of this Setup file, but also the prerequisites of the dependent Setup file *Tcl\_Basic.bawt*.

#### Debian Buster 10.2

- Install default Debian Buster 10.2 distribution (*debian-10.2.0-amd64-DVD-1.iso*)
- Use `apper` to install further packages:

Setup file	Debian package	Needed by library
<i>All</i>	build-essential	All C/C++ based libraries.
	curl	BAWT framework.
<i>Tcl_Basic.bawt</i>	libx11-dev	All X11 based libraries, ex. Tk.
	libcairo2-dev	tkpath
	freeglut3-dev	All OpenGL based libraries, ex. Canvas3D, Tcl3D
<i>Tcl_Extended.bawt</i>	libxrandr-dev	Tcl3D
<i>Tcl3D.bawt</i>	libXCursor-dev libXi-dev	glfw

	libXinerama-dev	
MiscLibs.bawt	libpython3.7-dev	boost
	bison flex	CERTI

## 2.3 Installation on Darwin

### Prerequisites:

- XCode
- curl (should be available by default on Mac)

### Downloads:

- **BAWT** framework *Bawt-1.2.0.zip*

### Installation:

- Extract **BAWT** framework *Bawt-1.2.0.zip* in a folder of choice, ex. */opt/Bawt*
- Open shell (Terminal window), go into created folder */opt/Bawt Bawt-1.2.0* and execute:

```
> chmod u+x Build*.sh
> chmod u+x tclkit*
```

### Usage examples:

Note, that Darwin does not support 32-bit programs.

- Create basic Tcl packages for 64-bit:
 

```
> ./Build-Darwin.sh Setup/Tcl_Basic.bawt update
```
- Create extended Tcl packages including simple shell based installation script for 64-bit:
 

```
> ./Build-Darwin.sh Setup/Tcl_Distribution.bawt update
```

## 2.4 Use of Batch Scripts

As the **BAWT** framework is generic and has lots of command line options (see chapter [7 Command Line Options](#)), a batch or shell script for each supported platform is included in the distribution for ease of usage in the most common use cases:

- Build-Windows.bat
- Build-Linux.sh
- Build-Darwin.sh

These batch scripts have been used in the examples of the previous chapters and may serve as starting point for your own batch scripts suited exactly to your needs.

### Batch script *Build-Windows.bat*

```
@echo off

rem Default values for some often used options.
set OUTROOTDIR=../BawtBuild
set TCLKIT=tclkit-win32.exe
set NUMJOBS=%NUMBER_OF_PROCESSORS%

rem First 4 parameters are mandatory.
if "%1" == "" goto ERROR
```

```

if "%2" == "" goto ERROR
if "%3" == "" goto ERROR
if "%4" == "" goto ERROR

set ARCH=%1
set VSVERS=%2
set SETUPFILE=%3
set ACTION=%4
shift
shift
shift
shift

rem If no target is given, use target "all".
if "%1"==" " goto BUILDALL

rem Loop through the rest of the parameter list for targets.
set TARGETS=
:PARAMLOOP
rem There is a trailing space in the next line. It's there for formatting.
set TARGETS=%TARGETS%%1
shift
if not "%1"==" " goto PARAMLOOP
goto BUILD

:BUILDALL
if "%ACTION%"=="clean" goto WARNING
if "%ACTION%"=="complete" goto WARNING

set TARGETS=all

:BUILD

set ACTION=--%ACTION%
set OPTS=--rootdir %OUTROOTDIR% ^
        --architecture %ARCH% ^
        --compiler %VSVERS% ^
        --numjobs %NUMJOBS% ^
        --logviewer

rem Build all libraries as listed in Setup file.
CALL %TCLKIT% Bawt.tcl %OPTS% %ACTION% %SETUPFILE% %TARGETS%

goto EOF

:WARNING
echo Warning: This may clean or rebuild everything.
echo Use \"clean all\" or \"complete all\" to allow this operation.

:ERROR
echo.
echo Usage: %0 Architecture VisualStudio SetupFile Action [Target1] [TargetN]
echo Architecture : x86 x64
echo VisualStudio : gcc vs2008 vs2010 vs2012 vs2013 vs2015 vs2017 vs2019
echo Actions : clean extract configure compile distribute finalize
echo list complete update simulate touch
echo Default target : all
echo Output directory: %OUTROOTDIR%
echo.

:EOF

```

See also chapter [5.5 Advanced Batch Scripts](#) for examples of more complex batch scripts.

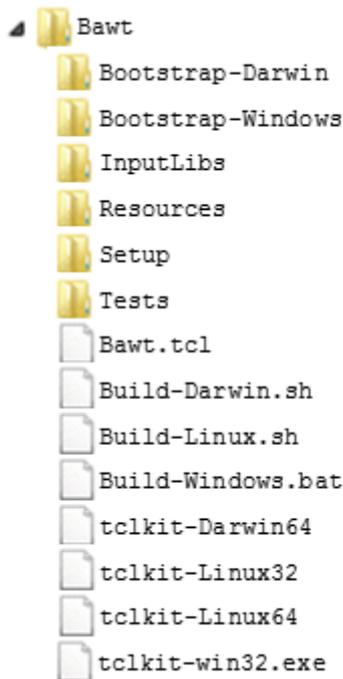

## 3 Directory and File Structure

This chapter explains the directory structure of the input and output files as well as the contents and structure of the *Setup* and *Build* files.

### 3.1 Directory Structure

#### 3.1.1 Structure of the input directories

If **BAWT** was downloaded and installed according to the instructions in chapter 2 *Installation and Usage*, the following directory structure should exist.

The *Bootstrap* directories contain zipped versions of the `7-zip` program for Windows and Darwin. In directory *Bootstrap-Windows* there should be at least one version of the MSYS/MinGW distributions, which you must have downloaded manually.

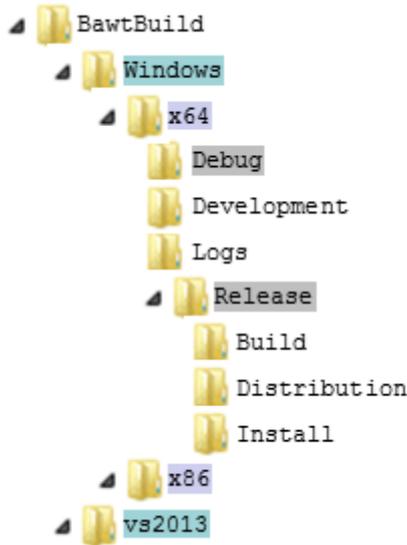

Directory *InputLibs* contains the zipped source code versions of the libraries and the associated *Build* files, see chapter 3.3 *Build Files* for a detailed description of *Build* files. Note, that this directory is empty after a fresh installation of **BAWT**, because the corresponding files are downloaded on demand at the first start of a **BAWT** build by default. See chapter 5 *Build Process* on how to avoid automatic downloads and updates.

The *Setup* files (see chapter 3.2 *Setup Files*) supplied with **BAWT** are located in directory *Setup*.

Directory *Tests* contains several simple test scripts for checking correct compilation and installation of Tcl related packages.

For each supported platform there is also a Tclkit executable supplied, which is needed to run the **BAWT** framework, if no Tcl interpreter is available on your machine (Bootstrapping). A Tclkit is a single-file Tcl interpreter executable.

### 3.1.2 Structure of the output directories

The root directory of the output files of a **BAWT** build (*BawtBuild* in the above example) can be specified with command line option `--rootdir`. In a *Build* script this directory can be queried with Tcl procedure *GetOutputRootDir*.

Beneath the root build directory there can be several directories named according to the build environment used: *Windows*, *Linux*, *Darwin* for builds with gcc or *vs2008*, *vs2010*, .. if a Visual Studio version was used for building.

Beneath these environment specific directories two directory names can appear, depending on the build architecture: *x86* for 32-bit or *x64* for 64-bit builds.

In the architecture specific directories 3 to 4 subdirectories are contained.

The *Logs* directory contains the overall build log file *\_BawtBuild.log* as well as the library specific build log files. See chapter [6 Logging](#) for an in-depth explanation of **BAWT** logging functionality.

The *Development* directory contains all the files needed for a developer using the built libraries. Depending on the specified build types, directories called *Release* and *Debug* will be created. These directories contain the *Build* and *Install* subdirectories, where the actual sources are extracted and built as well as a *Distribution* subdirectory, which will contain all files needed for a software distribution of the compiled libraries.

The *Distribution* and *Development* directories contain mostly identical content. The *Development* directory typically contains additional library include files and import files (*\*.lib*). It is the task of the library specific *Build* file to copy the needed files into the *Distribution* and *Development* directories.

### 3.1.3 Directory access

The next figure shows the input and output directory hierarchy together with the procedures which can be used to get the path to the corresponding directory. The first procedure column (grey boxes) shows the names used in BAWT versions prior to 1.0, the second column (green boxes) shows the names as used by BAWT 1.0 and newer.

The last column shows the available command line options to change the location of a specific input or output directory.

The library search paths, which can be obtained with procedure *GetInputLibsDirs* are set at BAWT startup to the following values:

- file join [GetInputRootDir] "InputLibs"
- file join [pwd] "InputLibs"

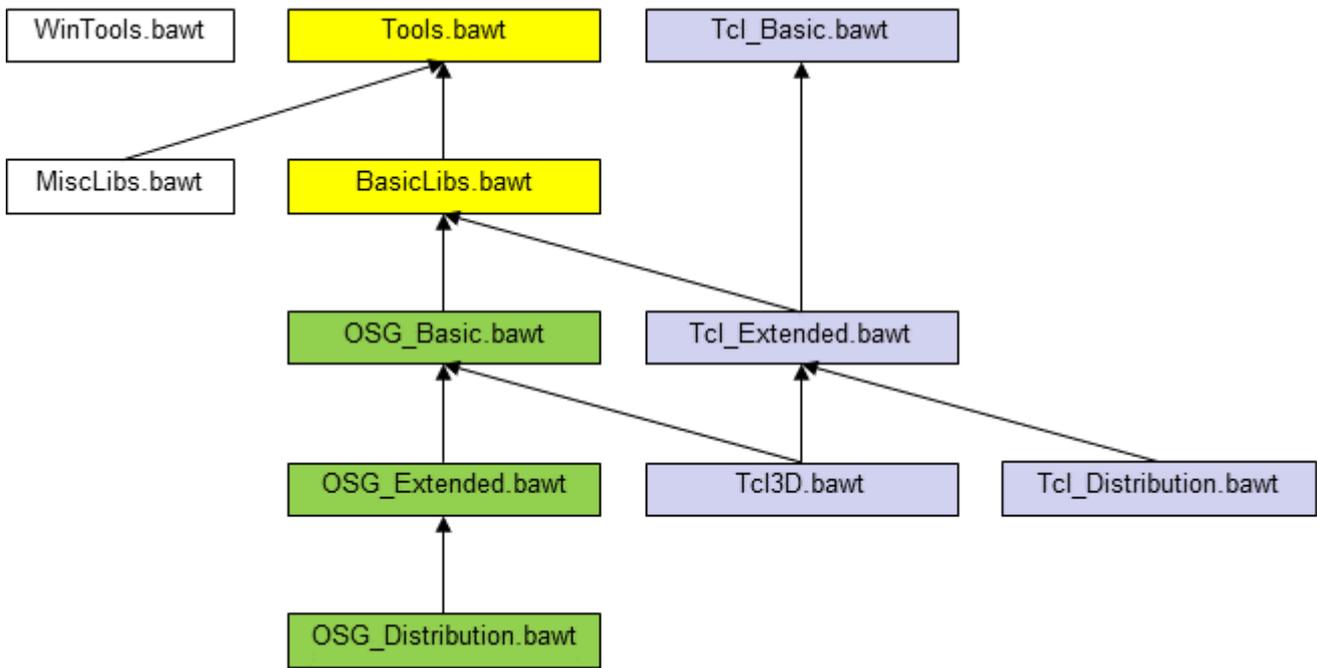

This list can be extended by using command line option [--libdir](#).

If command line option [--nosubdirs](#) is specified, procedures *GetOutputArchDir* and *GetOutputRootDir* return the same directory path.

See chapter [4 Build Stages](#) for an in-depth tour through the directory structure of **BAWT** in conjunction with the different build stages.

## 3.2 Setup Files

The following figure shows all available *Setup* files and their dependencies.

For the **Tcl** ecosystem the following 4 *Setup* files are currently supported.

<i>Tcl_Basic.bawt</i>	Builds Tcl, Tk, Starkit and Tcl/Tk packages, which do not depend on 3rd party libraries. On Windows all libraries can be compiled with MSys/MinGW.
<i>Tcl_Extended.bawt</i>	Builds all libraries of <i>Tcl_Basic.bawt</i> and Tcl/Tk packages which depend on 3rd party libraries, like SWIG, CMake, libressl or image libraries. On Windows all libraries can be compiled with MSys/MinGW.
<i>Tcl3D.bawt</i>	Builds all libraries of <i>Tcl_Extended.bawt</i> and the extended version of Tcl3D, which depends on 3rd party libraries like OpenSceneGraph, SDL, FTGL.
<i>Tcl_Distribution.bawt</i>	Builds all libraries of <i>Tcl_Extended.bawt</i> and creates an InnoSetup based setup file on Windows or an installation shell script on Unix.

For the **OpenSceneGraph** ecosystem the following 3 *Setup* files are currently supported.

<i>OSG_Basic.bawt</i>	Builds OpenSceneGraph with basic plugin libraries as needed by Tcl3D. On Windows all libraries can be compiled with MSys/MinGW.
<i>OSG_Extended.bawt</i>	Builds all libraries of <i>OSG_Basic.bawt</i> and builds OpenSceneGraph with extended plugin libraries, as well as libraries depending on OpenSceneGraph like osgEarth.
<i>OSG_Distribution.bawt</i>	Builds all libraries of <i>OSG_Extended.bawt</i> and creates an InnoSetup based setup file on Windows or an installation shell script on Unix.

Both the **OpenSceneGraph** ecosystem as well as the extended **Tcl** versions need special tools for building or basic libraries they depend upon.

<i>Tools.bawt</i>	Builds tools needed for building of libraries, like CMake or SWIG.
<i>BasicLibs.bawt</i>	Builds basic libraries needed by other libraries like several image libraries, zlib, freetype, ffmpeg and libressl.

There are 2 other *Setup* files not directly related to one of the above mentioned ecosystems.

<i>WinTools.bawt</i>	Convenience tools for Windows supplied as precompiled binaries like Vim or Doxygen.
<i>MiscLibs.bawt</i>	Builds miscellaneous libraries not directly related to Tcl or OpenSceneGraph like mathematical, geographical or XML libraries.

See the tables at the end of this chapter for the detailed content of the *Setup* files.

*Setup* files are standard Tcl script files. They must have one or more calls to the **BAWT** *Setup* procedure for each library being built. Optionally one or more calls to the **BAWT** *Include* procedure can be specified to add dependent libraries.

The *Setup* procedure has the following signature:

```
proc Setup { libName zipFile buildFile args }
```

The following 3 mandatory parameters must be specified:

- `libName`: Library name.
- `zipFile`: Zipped library source file or library source directory.
- `buildFile`: File containing build script for the library (see next chapter).

The following optional build parameters are currently supported:

<i>Release</i>	Build the Release version of the library. This is the default.
<i>Debug</i>	Build the Debug version of the library. Note, that not all libraries may support Debug mode.
<i>NoWindows</i>	Do not build the library on Windows.
<i>NoDarwin</i>	Do not build the library on Darwin.
<i>NoLinux</i>	Do not build the library on Linux.
<i>WinCompiler=winCompiler</i>	Specify the Windows compiler to use. Valid Windows compiler names are: gcc, vs. Note, that the <i>Build</i> file must have support for both VisualStudio and MSYS/MinGW instructions.
<i>ForceVS (Deprecated)</i>	Force using VisualStudio instead of using MSYS/MinGW. Note, that the <i>Build</i> file must have support for both VisualStudio and MSYS/MinGW instructions.
<i>Version=X.Y.Z</i>	Specify or override a version string for the library. Use this option, if building a library from a directory (ex. your repository workspace), which does not have a version number included in the directory name.
<i>MaxParallel=Platform:NumJobs</i>	Specify the number of parallel build jobs for a specific platform. Some build systems do not work correctly with lots of parallel builds. Valid platform names are: Windows, Linux, Darwin. The platform name may be optionally appended by the compiler type vs or gcc. Example: <code>MaxParallel=Windows-gcc:2</code>
<i>NoParallel=Platforms (Deprecated)</i>	Specify platforms as comma separated list for which parallel build should be disabled. Valid platform names are: Windows, Linux, Darwin.
<i>All other strings</i>	Strings not matching any of the above patterns are interpreted as a user configuration string. User configuration strings are appended to the CMake or configure commands of the library.

The next tables list the contents of the currently available *Setup* files.

**Setup file Tools.bawt**

```
# Builds tools needed for building of libraries, like CMake or SWIG.

# Setup LibName ZipFile BuildFile BuildOptions
Setup CMake CMake-3.17.3.7z CMake.bawt
Setup SWIG SWIG-4.0.2.7z SWIG.bawt
Setup yasm yasm-1.3.0.7z yasm.bawt
```

**Setup file BasicLibs.bawt**

```
# Builds basic libraries needed by several other libraries.

Include "Tools.bawt"

# All of the following libraries can be compiled on Linux or Darwin,
# but it is better to use the system provided libraries.

# Setup LibName ZipFile BuildFile BuildOptions

# Basic library needed by most other libraries.

### 3.3 Build Files

Build files include the logic needed to extract, configure, compile and distribute a library. They must define the following two procedures, where `libName` is replaced with the name of the library as specified as first parameter of the `Setup` procedure:

- `Init_libName { libName libVersion }`
- `Build_libName { libName libVersion buildDir instDir devDir distDir }`

The parameter values for these procedures are supplied by the **BAWT** framework.

<code>libName</code>	Library name as supplied with first parameter of procedure <code>Setup</code> .
<code>libVersion</code>	Library version extracted from source file name as supplied with second parameter of procedure <code>Setup</code> .
<code>buildDir</code>	<code>[file join [GetOutputBuildDir] \$libName]</code>
<code>instDir</code>	<code>[file join [GetOutputInstDir] \$libName]</code>
<code>devDir</code>	<code>[GetOutputDevDir]</code>
<code>distDir</code>	<code>[GetOutputDistDir]</code>

The logic of a `Build` file will be explained with the following excerpt of the `Build` file of Tcl package **udp**:

```

Build file udp.bawt
# Copyright: 2016-2019 Paul Obermeier (obermeier@tcl3d.org)
# Distributed under BSD license.

```

```
#
# BuildType: MSys / gcc

proc Init_udp { libName libVersion } {
    SetScriptAuthor    $libName "Paul Obermeier" "obermeier@tcl3d.org"
    SetLibHomepage     $libName "http://tcludp.sourceforge.net/"
    SetLibDependencies $libName "Tcl"
    SetPlatforms       $libName "All"
    SetWinCompilers    $libName "gcc"
}

proc Build_udp { libName libVersion buildDir instDir devDir distDir } {
    if { [UseStage "Extract" $libName] } {
        ExtractLibrary $libName $buildDir
    }

    if { [UseStage "Configure" $libName] } {
        TeaConfig $libName $buildDir $instDir
    }

    if { [UseStage "Compile" $libName] } {
        MSysBuild $libName $buildDir "install-binaries"
    }

    if { [UseStage "Distribute" $libName] } {
        LibFileCopy "$instDir" "$devDir/[GetTclDir]" "*" true
        LibFileCopy "$instDir" "$distDir/[GetTclDir]" "*" true
    }
    return true
}
```

The `Init_libName` procedure must call the following **BAWT** framework procedures:

<code>SetScriptAuthor</code>	Specify name and mail address of the build script author. This information is used for command line option <code>--authors</code> .
<code>SetLibHomepage</code>	Specify the homepage of the library. This information is used for command line option <code>--homepages</code> .
<code>SetLibDependencies</code>	Specify the dependencies of the library. If the library has no dependencies, specify <code>"None"</code> as parameter. Otherwise a variable number of library names can be given.
<code>SetPlatforms</code>	Specify the supported platforms. Valid keywords are: <code>"Windows"</code> <code>"Linux"</code> <code>"Darwin"</code> or <code>"All"</code>
<code>SetWinCompilers</code>	Specify the supported compilers on Windows. Optional. The first specified compiler is used as default. Valid keywords are: <code>"gcc"</code> <code>"vs"</code>

The `Build_libName` procedure must check, which stage or stages should be executed (using procedure `UseStage`) and supply appropriate Tcl commands for each stage.

The following four stages can be handled in a build file:

- Extract
- Configure
- Compile
- Distribute

See chapter 4 *Build Stages* for details on these stages and typical commands executed for each stage.

Errors can be indicated by calling the **BAWT** procedure `SetErrorMessage` and returning false.

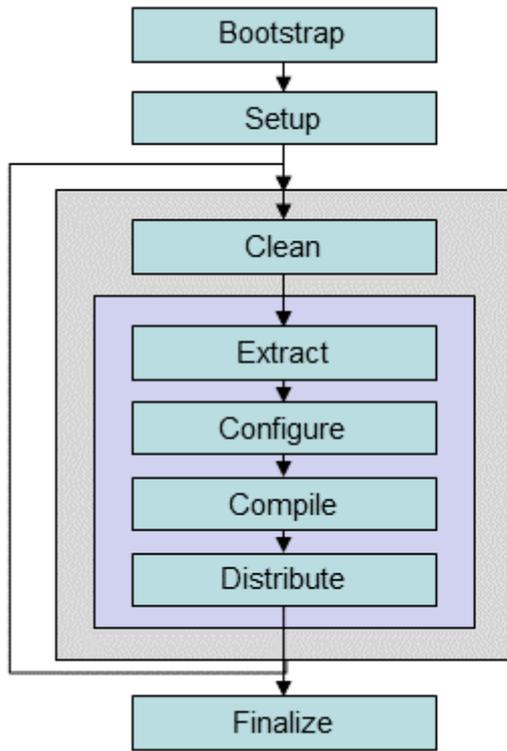

Optionally a procedure named `Env_libName` may be specified in a build file. This procedure has the same signature as the `Build_libName` procedure and may be used to specify library specific environment variables (using **BAWT** procedure `SetEnvVar`) or to add a value to the system environment variable `Path` (using **BAWT** procedure `AddToPathEnv`).

The following excerpt from the Tcl build file shows a usage example:

```
proc Env_Tcl { libName libVersion buildDir instDir devDir distDir } {  
    SetEnvVar      "TCLLIBPATH" "$devDir/[GetTclDir]/lib"  
    AddToPathEnv  "$devDir/opt/$libName/bin"  
}
```

## 4 Build Stages

This chapter describes the stages used in the **BAWT** framework to build the libraries specified in a *Setup* file.

The stages are grouped into global and library specific ones. The global stages `Bootstrap`, `Setup` and `Finalize` are called only once per **BAWT** execution, the library specific stages are called once for each library.

Four of the library specific stages (`Extract`, `Configure`, `Compile`, `Distribute`) are user configurable. Actions for these stages must be specified in the library *Build* files.

### 4.1 Stage Bootstrap

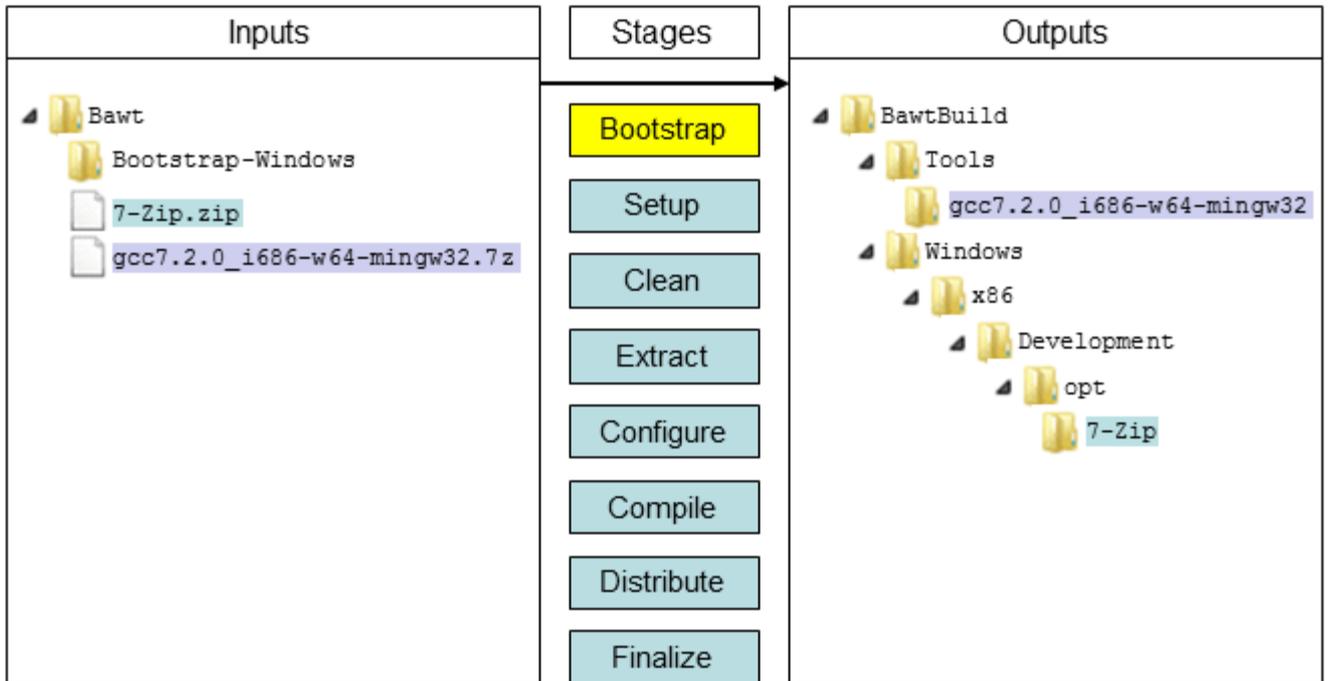

Extract and copy bootstrap tools.

This stage is executed automatically on each invocation of *Bawt.tcl*.

It is not executed, if command line option `--list` is specified.

**BAWT** needs the **7-Zip** program to extract the library source distributions. For Windows and Darwin a version of the **7-Zip** program is included in the **BAWT** framework. On Linux **7-Zip** is typically already available with the operating system or can be installed as Linux package `p7zip` or `p7zip-full`.

On Windows lots of the libraries are built with the MSys/MinGW suite. Different versions of MSys/MinGW are available on the **BAWT** download site.

Command line options influencing this stage:

[--gccversion](#)  
[--architecture](#)  
[--toolsdir](#)

The 7-Zip distribution itself must be compressed with standard ZIP, so that it can be extracted with the `vfs::zip` package contained in the `tclkit`. All other tools and libraries are compressed in 7-Zip format because of better compression rates (Example: MSys/MinGW is 2 times smaller with 7z).

## 4.2 Stage Setup

Read and execute specified *Setup* file.

This stage is executed automatically on each invocation of *Bawt.tcl*.

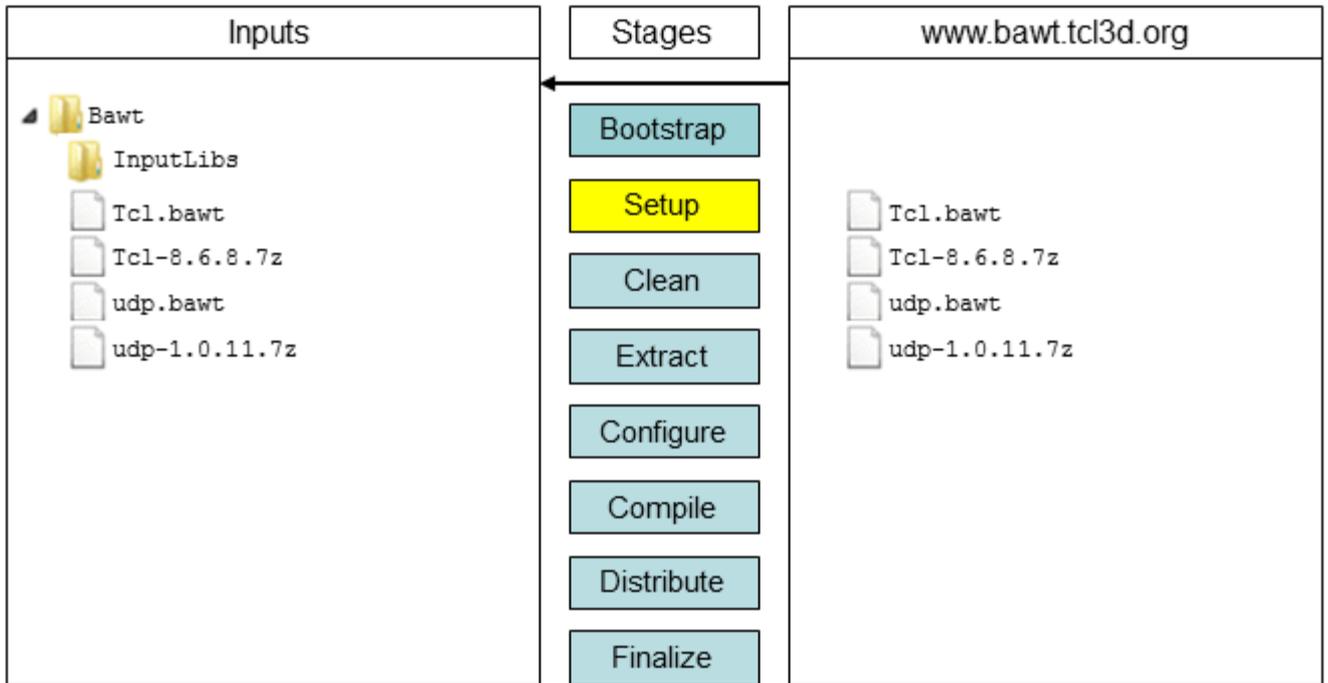

Check for existence of the library source code (either as a 7z file or directory) as well as the according *Build* file. If these do not exist in the library directory *InputLibs* of the current working directory (additional directories can be added with command line option [--libdir](#)) or are older than those available on the **BAWT** website, they are downloaded from the **BAWT** website.

If this fails, a fatal error is thrown and the build process is stopped.

The version number of the library is extracted from the file or directory name of the library.

If build action is set to *Update*, the necessary build stages are determined according to the existence of the library source and *Build* files as well as to the modification times of the corresponding build and install directories.

Checking for newer versions and automatic downloading may be skipped by specifying command line option [--noonline](#).

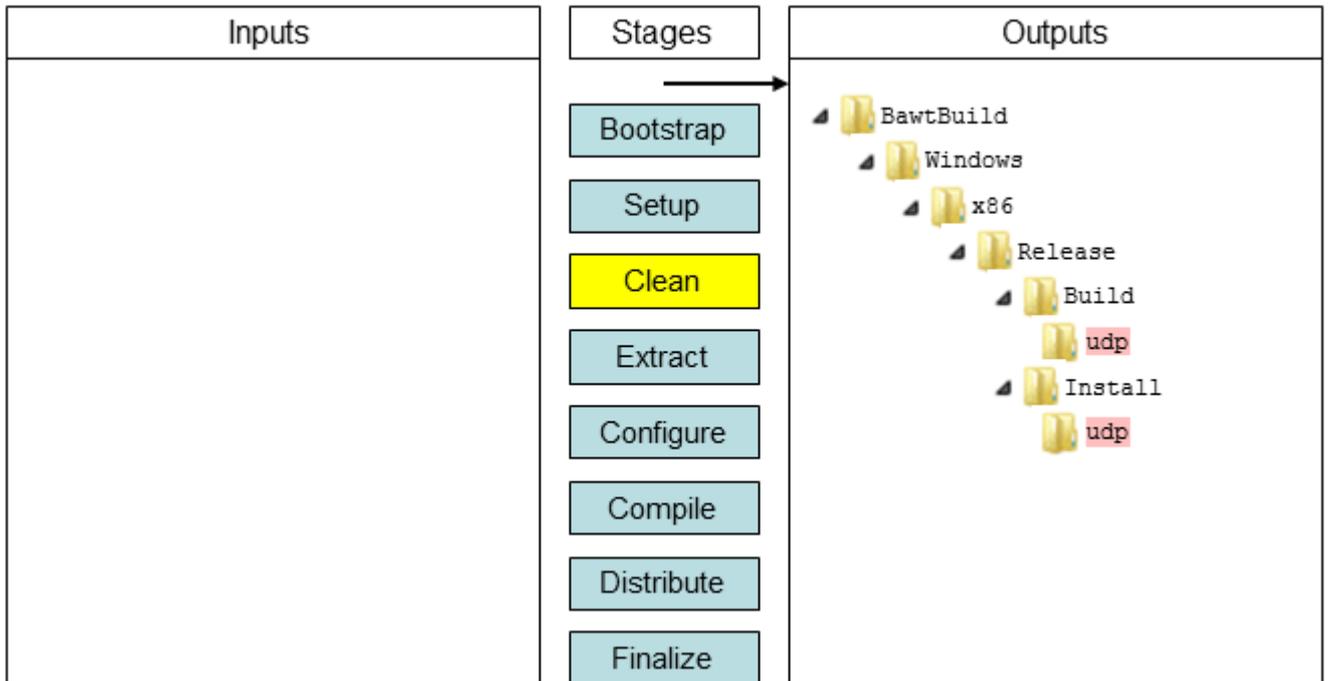

Command line options influencing this stage:

- [--noonline](#)
- [--norecursive](#)
- [--sort](#)
- [--url](#)

### 4.3 Stage Clean

Remove library specific build and install directory.

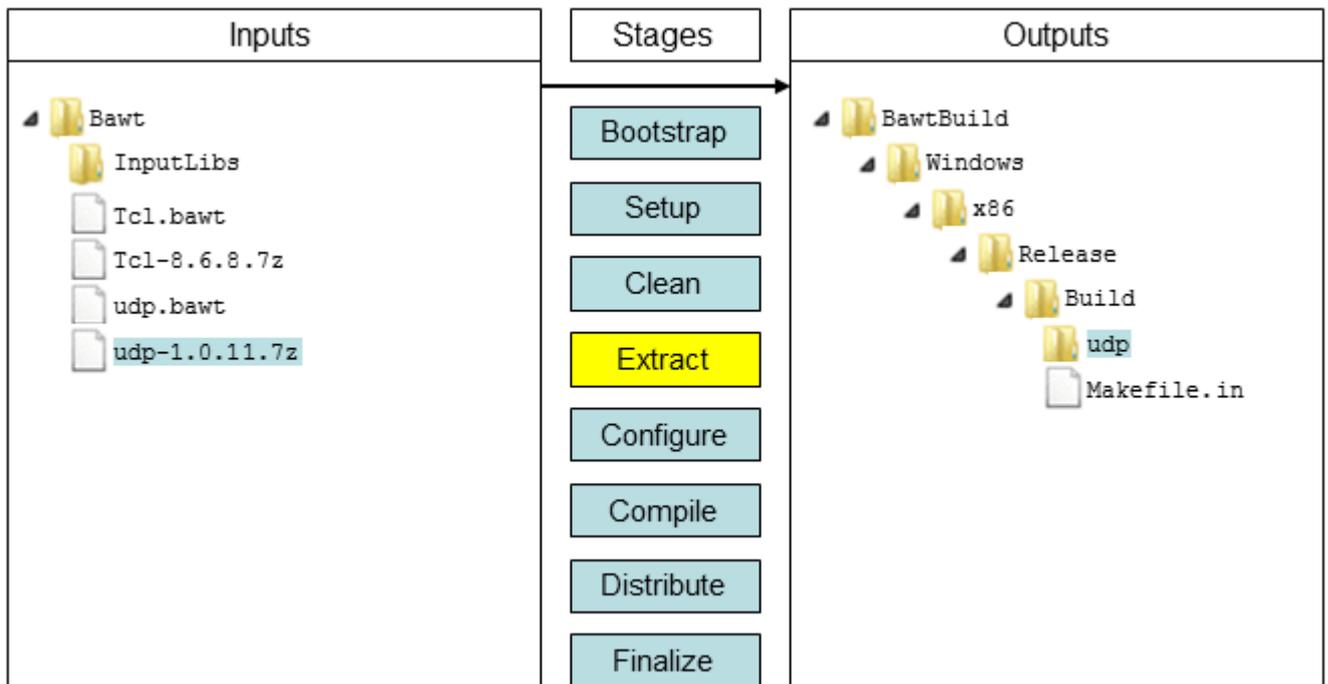

Command line options influencing this stage:

- [--clean](#)
- [--timeout](#)

## 4.4 Stage Extract

Extract library source code into build directory.

In stage `Extract` the library source code will be extracted and copied into the build directory. This is achieved by calling the **BAWT** procedure `ExtractLibrary`, which cares about having either a source directory or a compressed source file.

Ideally the source code can be compiled without any changes. If changes have to be done, it is preferred not to edit the source code manually, but make the changes in the build script after extraction.

**BAWT** has two utility procedures for this purpose:

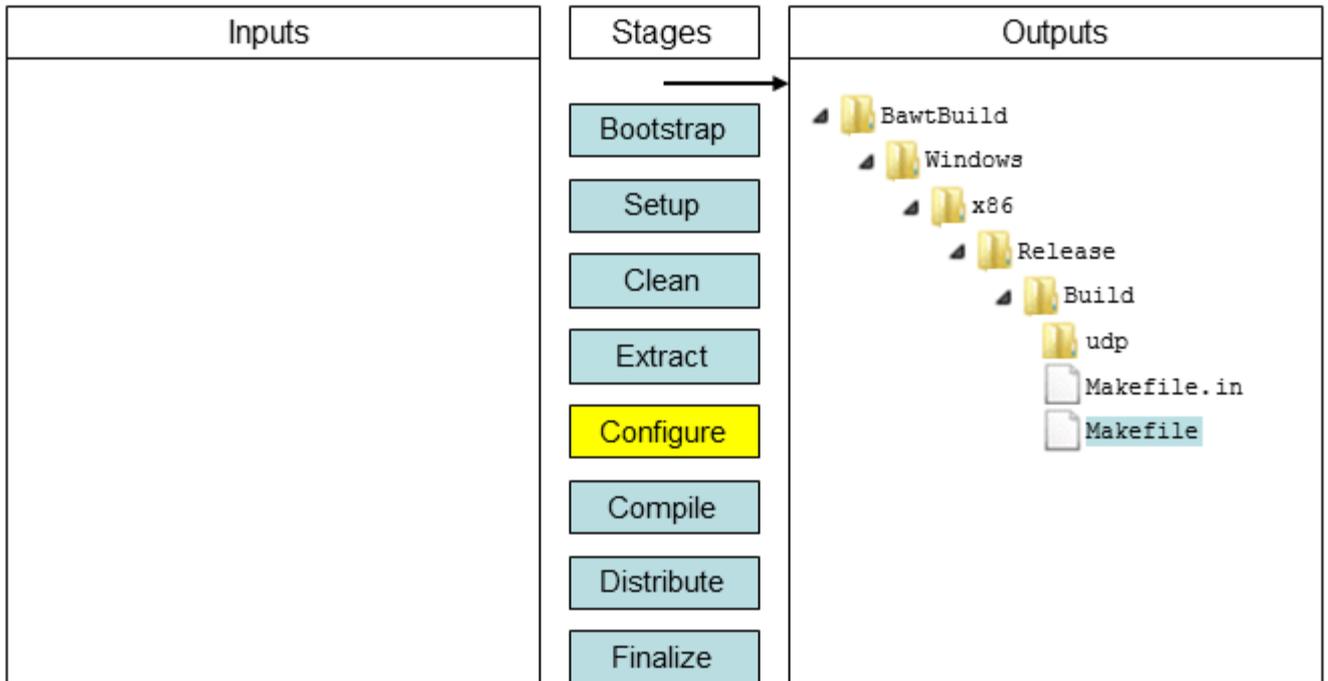

- `ReplaceLine`
- `ReplaceKeywords`

Command line options influencing this stage:

[`--extract`](#)

## 4.5 Stage Configure

Configure library for compilation.

In stage `Configure` the library will be configured, which generates the appropriate make files for the chosen compiler and platform.

The following high-level **BAWT** procedures are available for configuration tasks:

*CMakeConfig* when using the CMake build infrastructure.

*MSysConfig* when using a configure script with “standard” options.

*TeaConfig* when using the Tcl Extension Architecture for Tcl packages.

See the source code of *Bawt.tcl* to get the default options set by these procedures.

If the build infrastructure does not fit any of the mentioned one above, the configuration command must be built up as a Tcl string and executed with the generic **BAWT** procedure *MSysRun*.

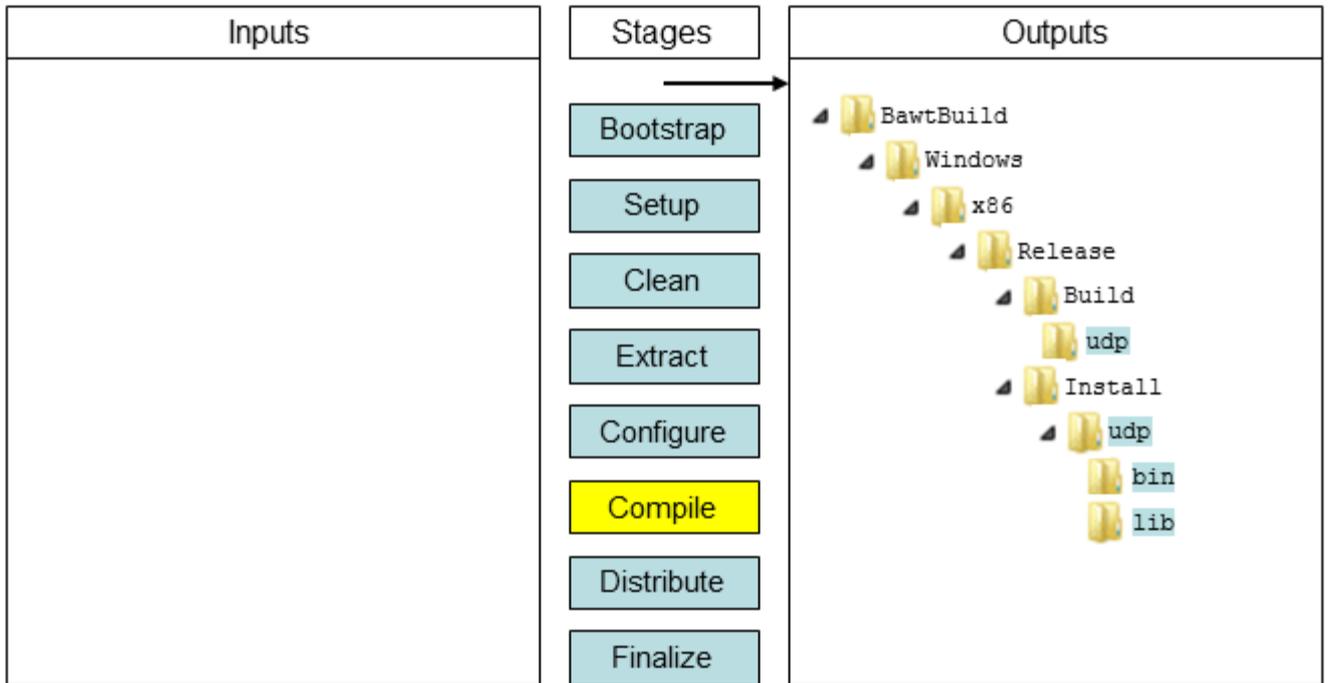

See the miscellaneous build scripts for usage examples.

Command line options influencing this stage:

[--configure](#)  
[--architecture](#)  
[--compiler](#)  
[--gccversion](#)  
[--buildtype](#)  
[--copt](#)

## 4.6 Stage Compile

Compile and install library.

In stage `Compile` the library will be compiled and installed.

The following high-level **BAWT** procedures are available for compilation tasks:

*CMakeBuild* when using the CMake build infrastructure.

*MSysBuild* when using the Tcl Extension Architecture for Tcl packages.

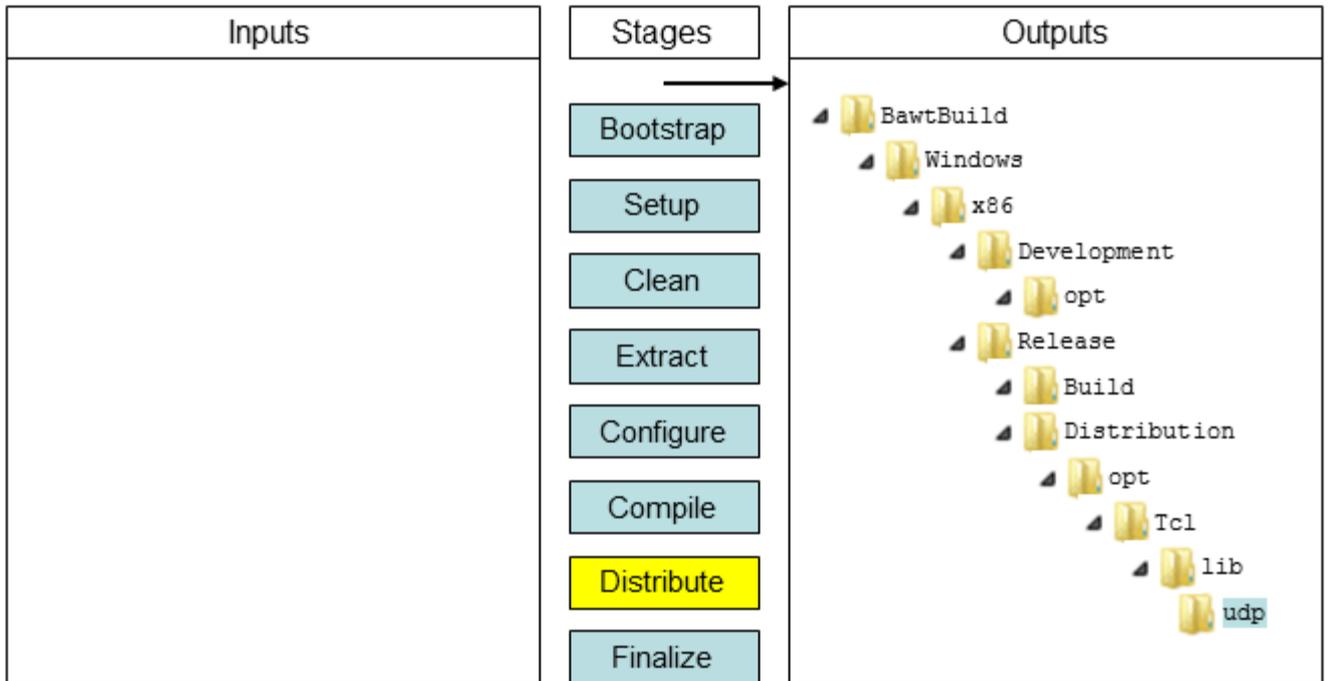

If the build infrastructure does not fit any of the two mentioned above, the compilation command must be built up as a Tcl string and executed with either **BAWT** procedure *MSysRun* or *DosRun*.

Command line options influencing this stage:

- [--compile](#)
- [--numjobs](#)
- [--nostrip](#)
- [--noimportlibs](#)

## 4.7 Stage Distribute

Copy relevant files into developer and user distribution directories.

In stage `Distribute` the library will be copied into the distribution and development directories.

The following **BAWT** procedures are typically used for distribution tasks:

```

SingleFileCopy
MultiFileCopy
LibFileCopy
FileRename
UseTclPkgVersion
IsDebugBuild
IsReleaseBuild
IsWindows
IsLinux
IsDarwin
IsUnix
ErrorAppend

```

Command line options influencing this stage:

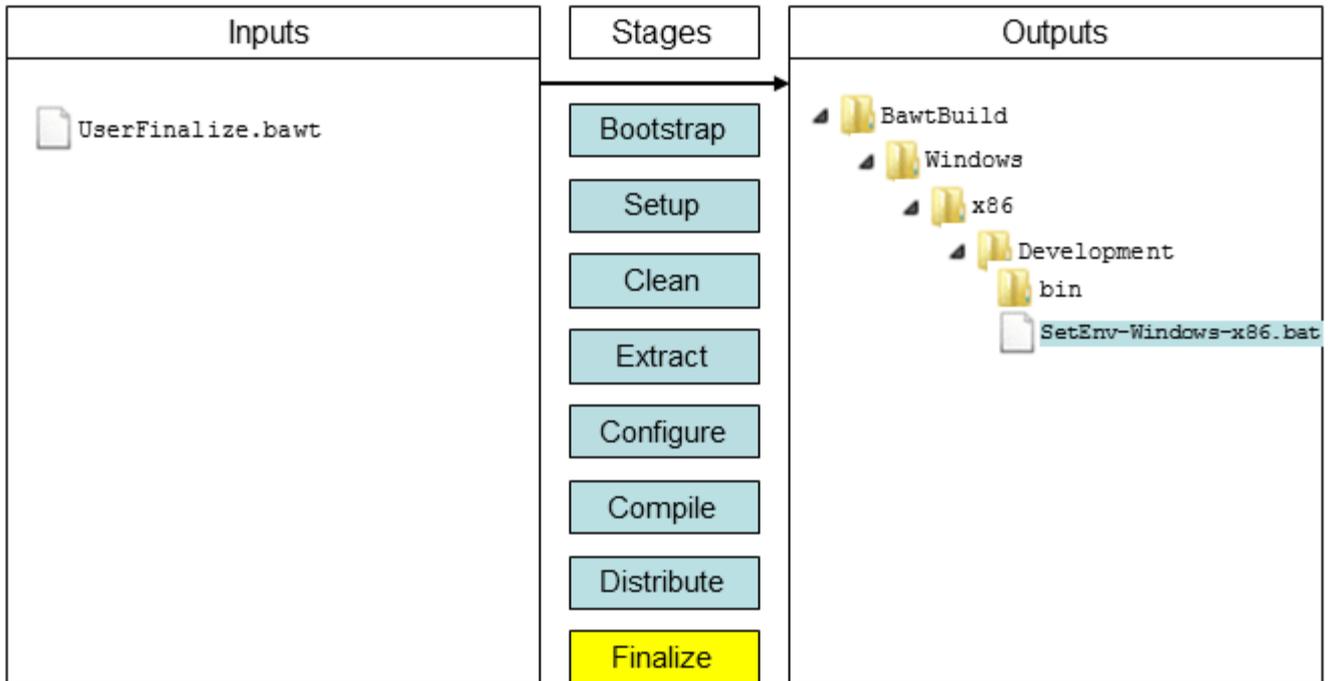

```

--distribute
--noverion

```

## 4.8 Stage Finalize

Perform final actions, optionally call user supplied `Finalize` procedure and print summary.

The Finalize stage is performed automatically at the end of the build process or can be manually selected with command line option [--finalize](#).

The Finalize stage creates an environment file in the `Development/bin` directory called `SetEnv-*.bat` or `SetEnv-*.sh`. It contains all the environment variables set by the `Env_libName` procedures of the libraries.

If running on Windows with Visual Studio it also copies the appropriate Visual Studio runtime libraries into the `Development/bin` directory. If you do not want to copy these runtime libraries, use command line option [--noruntimelibs](#).

To supply a user defined finalize action to **BAWT**, create a file containing a procedure named `Finalize`. See the file `UserFinalize.tcl` in **BAWT** directory `Setup` as an example.

You can use any standard Tcl procedure or one of the **BAWT** procedures like `Log` or `MultiFileCopy` in the `Finalize` procedure.

To make the file containing your Finalize procedure available for the **BAWT** build process, use command line option [--finalizefile](#).

Command line options influencing this stage:

[--finalize](#)  
[--finalizefile](#)  
[--noruntimelibs](#)

## 5 Build Process

This chapter gives insight into the BAWT build process from the perspective of a user of BAWT as well as from the perspective of a developer, who wants to extend BAWT with new libraries.

### 5.1 User Perspective

As described in the previous chapter a specific stage can be executed with one of the following command line action options. These specific action options are typically only used when integrating a new library into BAWT.

```

--clean      : Clean library specific build and install directories.
--extract    : Extract library source from a ZIP file or a directory.
--configure  : Perform the configure stage of the build process.
--compile    : Perform the compile stage of the build process.
--distribute : Perform the distribution stage of the build process.
--finalize   : Generate environment file and call user supplied Finalize procedure.

```

The following global command line action options are typically used for building or updating the BAWT libraries.

```

--complete  : Perform the following stages in order:
              clean, extract, configure, compile, distribute, finalize.
--update    : Perform necessary stages depending on modification times.
              Note: Global stage finalize is always executed.
--simulate  : Simulate update action without actually building libraries.
--touch     : Set modification times of library build directories to current time.

```

Option `--complete` makes a complete rebuild of the specified libraries, while `--update` checks, which libraries have to be rebuilt.

The necessary build stages are determined according to the existence of the library source and *Build* files as well as to the modification times of the corresponding build directories.

It is also checked, if the build of a library has been cancelled or stopped by checking for the existence of a so called *Progress File*, which is created in the *Logs* directory at the start of a library build and deleted after a successful library build.

Additionally a check is performed, if a library is dependent of another library, which has been rebuilt. This recursive dependency checking can be switched off with command line option `--norecursive`.

The `--simulate` option performs the same actions as the `--update` option, but does not build anything. It just prints out, which libraries would be rebuilt, if you would execute the `--update` command line option.

It often happens, that only cosmetic changes are done to a *Build* file, which would cause this library (and all dependent libraries) to be rebuilt. To avoid rebuilding of these libraries, specify the option `--touch`, which sets the modification times of the build and install directories to the current date and time.

#### 5.1.1 Use Case: Cosmetic change of Build file CMake.bawt

Due to the amount of dependencies, a change of *Build* file *CMake.bawt* would cause a lot of libraries to be rebuilt, as the next screenshot of the *BawtLogViewer* shows, when executing a `--simulate` run.

The screenshot shows the BAWT Setup window titled "BAWT - Setup File C:/poSoft/Bawt/Setup/AllLibs.bawt". The window contains a table of 106 libraries and a log file viewer.

#	Build-#	Library Name	Version	Build time	Mod. time	Update cause	Stages

## 5.1.2 Compilation without Visual Studio

Compilation of **Tcl/Tk** and all supported Tcl packages (everything included in *Setup* files *Tcl\_Basic.bawt* and *Tcl\_Extended.bawt*) is possible without using Visual Studio with the exception of building VisualStudio compatible Tcl and Tk stub libraries. Those stub libraries can only be compiled using Visual Studio.

To generate VisualStudio compatible Tcl and Tk import libraries (\*.lib) the **BAWT** procedure *Dll2Lib* is used. It creates the import library from the DLL by using the **link.exe** program, which is part of Visual Studio.

If Visual Studio is not available, a warning message like the following is issued:

```
Warning > Dll2Lib tk86.lib: Creating import libraries needs VisualStudio
```

To avoid these warnings, add command line option `--noimportlibs`, if Visual Studio is not available or import libraries are not needed.

## 5.1.3 Avoid online updates of libraries

To have a consistent set of library versions or if using **BAWT** on a computer without internet connection, use the command line option `--noonline` to avoid checking for updates and automatic downloading of new libraries.

### 5.1.4 Use the generated libraries

To use the generated libraries there are the following possibilities:

1. Manually copy the appropriate directory.
2. Use the *Finalize* procedure.
3. Create a software distribution setup file

#### **Manually copy the appropriate directories**

Copy the appropriate directories from either the *Distribution* or *Development* directory to a suitable location or your computer.

For example, after executing the Setup file *Tcl\_Basic.bawt* to generate a **Tcl** distribution for Windows, copy output directory *Development\opt\Tcl* to *C:\Tcl* and set the environment variables `PATH` and `TCLLIBPATH`.

*Note, that the entries of the `PATH` variable on Windows are separated by semicolons (;). The entries of variable `TCLLIBPATH` are separated by spaces and directory paths must use slashes (/) instead of backslashes (\).*

*On Unix the environment variables are typically set in the shell resource file, ex. `.bashrc`:*

#### **Use the Finalize procedure**

Instead of doing the copy manually, it is easier and quicker to do the copying in the Finalize stage. The **BAWT** framework contains a template Finalize file *Setup/UserFinalize.bawt*, which is shown below. Adapt the installation paths according to your local needs.

```
# Example script for user supplied Finalize procedure.
#
# The procedure copies the generated Tcl distribution
# from the Development folder into a folder specified
# in your Path environment variable.
#
# You have to adapt the installation paths (tclRootDir)
# according to your needs.
#
# To execute the Finalize procedure, the name of this file
# must be specified on the BAWT command line with option
# "--finalizefile".

proc Finalize {} {
    Log "Finalize (User defined)"

    # For safety reasons this is just a dummy mode.
    # Remove the next lines to enable functionality.
    if { 1 } {
        Log "Finalize Dummy mode" 2 false
        return
    }

    if { [IsWindows] } {
        set tclRootDir "C:/opt"
    } elseif { [IsLinux] } {
        set tclRootDir "~/opt"
    } elseif { [IsDarwin] } {
        set tclRootDir "~/opt"
    } else {
```

```
    ErrorAppend "Finalize: Cannot determine operating system" "FATAL"
}

set tclInstDir [file join $tclRootDir "Tcl"]

Log "Installing Tcl into $tclInstDir" 2 false
DirDelete $tclInstDir

MultiFileCopy [file join [GetOutputDevDir] [GetTclDir]] $tclInstDir "*" true
}
```

### **Create a software distribution setup file**

There are currently two *Build* files to create software distribution setup files:

- *SetupTcl.bawt* to create a **Tcl** Batteries Included software distribution
- *SetupOsg.bawt* to create an **OpenSceneGraph** software distribution

These scripts take all contents of the *Release/Distribution* directory and create a software distribution setup file. This setup file is created with **InnoSetup** for Windows platforms and as a simple, self-extracting shell script for Unix platforms.

The software distribution setup file itself is generated in the *Release/Distribution* directory.

The software distribution setup file name for **Tcl/Tk** has the Tcl version, the architecture and the BAWT version used to build the distribution encoded into the file name.

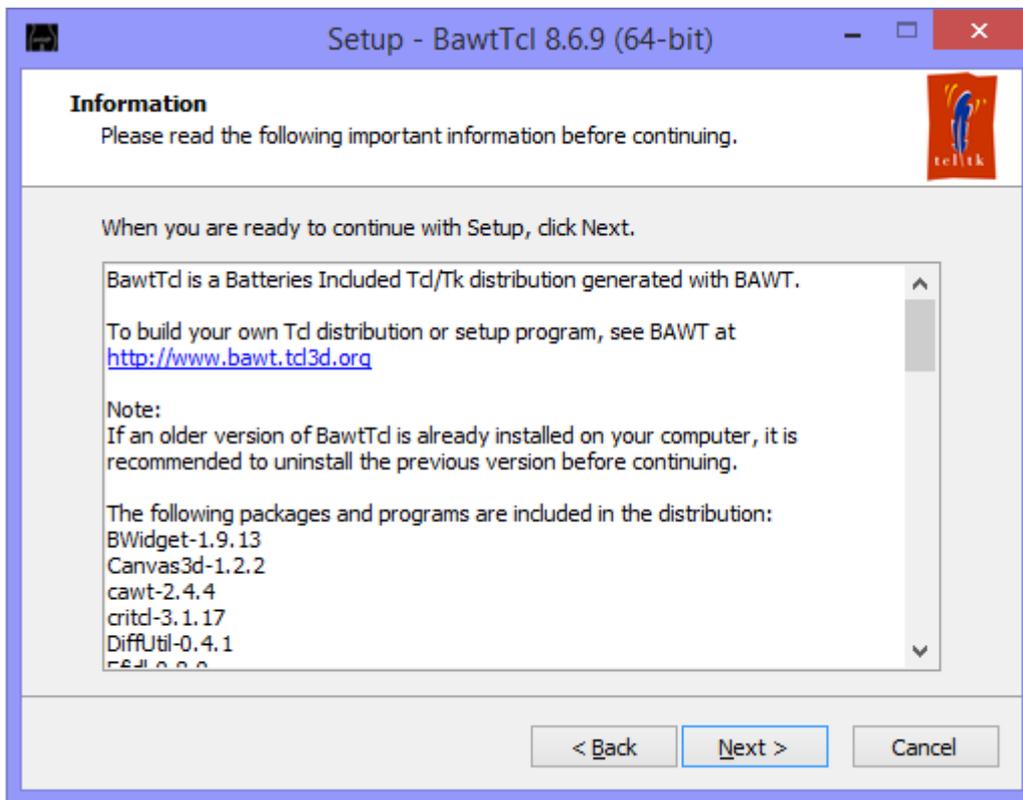

Example: `SetupTcl-8.6.10-x64_Bawt-1.1.2.exe`

The software distribution setup file name for **OpenSceneGraph** has the OSG version, the compiler version, the architecture and the BAWT version used to build the distribution encoded into the file name.

Example: `SetupOsg-3.4.1-vs2013-x64_Bawt-1.1.2.exe`

In the same directory as the distribution setup files, text files named *SetupTcl-8.6.10.txt* resp. *SetupOsg-3.4.1.txt* are created, which list the contents of the software distribution setup file.

This list is used to display the contents of the **InnoSetup** based distribution setup file, see the following screenshot for an example.

For Unix (Linux and Darwin) a simple shell script based distribution setup file is generated. If called without arguments, a simple usage message is displayed.

```
> ./SetupTcl-8.6.10-x64_Bawt-1.1.2.sh

Usage: SetupTcl-8.6.10-x64_Bawt-1.1.2.sh InstallationDirectory
Install folder Tcl into specified installation directory
```

If called with a not existing installation directory path, an error message is printed onto standard output.

```
> ./SetupTcl-8.6.10-x64_Bawt-1.1.2.sh asdf

Installation directory asdf does not exist.
Check name or create manually.
```

If called with a valid installation directory, the contents are extracted into that directory and a message on how to set the needed environment variables is printed onto standard output.

```
> ./SetupTcl-8.6.10-x64_Bawt-1.1.2.sh ~/bin
Extracting Tcl into /home/obermeier/bin ...

Add the following lines to your shell resource file (ex. ~/.bashrc):
export PATH="/home/obermeier/bin/Tcl/bin:$PATH"
export TCLLIBPATH="/home/obermeier/bin/Tcl/lib $TCLLIBPATH"
```

## 5.1.5 Change icons of executables

To change the icon of the generated tclkits and starpacks as well as the information shown about an executable on Windows (Resource), two command line options exist in the **BAWT** framework:

- [--iconfile](#)
- [--resourcefile](#)

Use the icon file *poSoft.ico* and resource file *poSoft.rc* supplied by **BAWT** in directory *Resources* as starting point for your adapted ones.

If specifying your own resource file, do not change the name of the icon file in the following line of your resource file:

```
tk ICON DISCARDABLE "tclkit.ico"
```

The name must always be *tclkit.ico*.

If specifying a user supplied icon file with command line option `--iconfile`, the icon file will be copied into the build directory *Tclkit/kbskit/win* and renamed to *tclkit.ico*, so that it is possible to only specify an icon file without specifying a resource file.

*Changes to the used icon and resource file are not considered by the BAWT update check process, so if using these options it is necessary to at least rebuild package tclkit and its dependencies.*

### 5.1.6 Parallel builds

All build environments used by BAWT support parallel compilation. The number of parallel build jobs can be specified globally for all libraries with command line option `--numjobs`. Alternatively, the number of parallel build jobs can be restricted for specific libraries as additional parameter `MaxParallel` in the Setup procedure. See chapter [3.2 Setup Files](#) for a description of the Setup procedure and its parameters.

The following libraries consistently produce deadlocks when executed in parallel, so the number of parallel jobs is already limited in the corresponding BAWT Setup files.

Library	Setup settings
CERTI	MaxParallel=Windows-gcc:5
PNG	MaxParallel=Windows-gcc:1
OpenSceneGraph	MaxParallel=Windows-gcc:1
tserialport	MaxParallel=Windows-gcc:1

Other libraries which occasionally tend to deadlock are the following:

- freeglut
- openjpeg
- SDL

*Deadlocks have occurred until now only on Windows using the gcc compiler.*

As reference point, the next table shows typical build times on my laptop for libraries needing 2 minutes or more. The laptop is equipped with an Intel QuadCore i7-4700 2.4Ghz with HyperThreading. 8 parallel compile jobs have been used.

Estimated build time	Libraries
~ 2 minutes	libgd tcl3dFull SetupTcl
~ 3 minutes	geos kdis TIFF
~ 4 minutes	SWIG tcltcl tcl3dFull
~ 5 minutes	gdal Tclkit Xerces
~ 6 minutes	curl gdal libressl Tcl
~ 7 minutes	boost ffmpeg Img
~ 9 minutes	fftw
~ 25 minutes	osgearth
~ 35 minutes	OpenSceneGraph

## 5.2 Developer Perspective

### 5.2.1 Upgrade a library

If you want to use a new version of a library already supported by **BAWT**, chances are high, that the existing build scripts still work with the new version.

So just pack the sources of the new version into a 7z file and edit the corresponding entry in the *Setup* file. Also check the comments of the library build script regarding manual changes to the source code.

If the library is a **Tcl** package, you might get warnings from the **Starpack** build scripts. This indicates, that you will have 2 different versions in the **Tcl** library directory, which might lead to troubles.

The following warnings are issued, when upgrading library tablelist 6.0 to tablelist 6.3:

```
MakeStarpack: Found more than 1 package with prefix tablelist*:
  TclBasic-8.6.10/vs2013/x64/Development/opt/Tcl/lib/tablelist6.0
  TclBasic-8.6.10/vs2013/x64/Development/opt/Tcl/lib/tablelist6.3
```

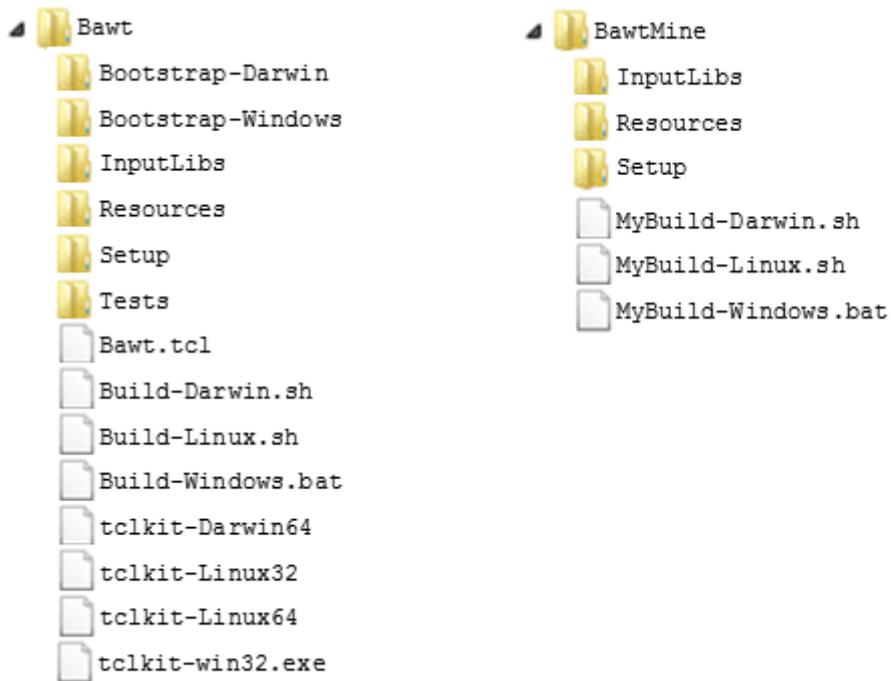

So, when upgrading one or more libraries, you should either remove the development and distribution directories and do a fresh rebuild. The other possibility is to search for the directories of the old version (*tablelist6.0* in the above example) and just remove these directories from the development and distribution directory.

Another option is to use command line option [--noverion](#), which strips the version number from the names of Tcl package directories.

### 5.2.2 Add a library

Library sources should be specified either as a directory named *\$libName-\$libVersion* or as a compressed file named *\$libName-\$libVersion.7z*.

It is easily possible to extend the libraries compiled by **BAWT** with COTS software, ex. company specific libraries. One possibility is to just add these libraries into the *InputLibs* directory of the standard **BAWT** distribution. The better solution is to create a separate directory (ex. *BawtMine*), which holds your libraries in a similar structure like **BAWT** does. In this directory you create adapted versions of the batch scripts (ex. *MyBuild-Windows.bat*) and add *Setup* files, which reference your libraries as well as libraries of the standard BAWT distribution.

If you want to use a library, which is currently under development, it is possible to add the directory containing ex. the local checkout of the library.

The following example shows the *Setup* file *mawtSvn.bawt* used to compile the current version of **MAWT** from my local SVN checkout.

```

Include "Tools.bawt"
Include "BasicLibs.bawt"
Include "Tcl_Basic.bawt"

if { [IsWindows] } {
    set dirName C:/poSoft/Mawt
} elseif { [IsLinux] } {
    set dirName /home/obermeier/poSoft/Mawt
} else {
    set dirName /Users/obermeier/poSoft/Mawt
}
Setup mawt $dirName mawt.bawt Version=0.4.0

```

*Note, that the checkout directory typically has no version number in it, so the version number is specified as optional argument of the Setup procedure.*

### 5.2.3 Add a Tcl program

Adding a Tcl program is similar to adding a library, i.e. the sources must be supplied as a compressed file as well as a corresponding Build script.

The Tcl program will be created as a starpack, i.e. a standalone executable containing the Tcl interpreter (tclkit), the program scripts as well as needed Tcl packages.

To ease the generation of starpacks, the BAWT framework offers procedures *MakeStarpacTcl* and *MakeStarpacTk* for this purpose. Use *MakeStarpacTcl*, if you want to create a console program, and *MakeStarpacTk*, if you want to create a program with a graphical Tk user interface.

```
proc MakeStarpacTcl { appScript appName starpackName buildDir args }
```

<i>appScript</i>	Full path to the startup script of the Tcl program.
<i>appName</i>	The name of the application. Typically <code>\$libName</code> .
<i>starpackName</i>	The name of the starpack executable. Typically <code>\$libName[GetExeSuffix]</code> .
<i>buildDir</i>	The name of the output directory. Typically <code>\$instDir</code> .
<i>args</i>	A list of files and directories to be included in the starpack. The path names of the files and directories must be absolute paths. The files of the Tcl program are typically located in <code>\$buildDir</code> . Needed Tcl packages are located in <code>[GetDevTclLibDir]</code> .

Example Build files using these procedures are:

- *BawtLogViewer.bawt*
- *gorilla.bawt*
- *poApps.bawt*
- *tclsg.bawt*
- *tksqlite.bawt*

*The signature of procedure `MakeStarpackTk` is identical to procedure `MakeStarpackTcl`.*

*A starpack on Darwin is a directory using the extension `.app`.*

## 5.2.4 Manually compile a library

To configure and compile a library, the **BAWT** framework uses shell (\*.sh) or batch files (\*.bat). These batch files are created in the *Configure* and *Compile* phases and stored in the *Build* directory (or a suitable subdirectory like eg. *win*) of the library.

You can use these batch files to configure or compile a library manually. This is especially useful while developing the build file for a new **BAWT** library.

*Before running one of the shell or batch files on the command line, you have to remove the last line of the script containing the `exit` command or replace the `exit` command with an `echo` command.*

*You can easily open a library specific DOS or MSys shell window via the context menu of the BawtLogViewer, see chapter 6.1 Graphical Log Viewer.*

The first part of the file name defines the configure and compile environment and corresponds to the general **BAWT** procedures for executing commands with the same name:

*\_Bawt\_DosRun:*

- The commands will be executed in a standard Windows command line environment.
- If running the command manually on Windows, it must be executed from a DOS command shell.
- Example: `> _Bawt_DosRun_CMakeBuild.bat`

*\_Bawt\_MSysRun:*

- The commands will be executed in the MSys/MinGW environment or a standard shell environment on Unix systems.
- If running the command manually on Windows, it must be executed from a MSYS/MinGW shell.
- Note, that on Unix systems all files are prefixed with `_Bawt_MSys`.
- Example: `> sh _Bawt_MSysRun_MSysBuild.bat`

The second part specifies the caller of the *DosRun* or *MSysRun* command. This is typically one of the following standard BAWT procedures:

- `NMakeBuild`
- `MsBuild`
- `CMakeConfig`

- CMakeBuild
- MSysConfig
- TeaConfig
- MSysBuild

For libraries, which cannot be built with one of the above standard procedures, it is common usage to specify the caller in the form:

- `_Bawt_LibName_Configure`
- `_Bawt_LibName_Compile`

One example is the Boost library, which has special configure and compile commands:

- `_Bawt_DosRun_Boost_Configure.bat`
- `_Bawt_DosRun_Boost_Compile.bat`

When using NMakeBuild or MsBuild, there is no need to specify commands for the configuration phase.

- `_Bawt_DosRun_MsBuild.bat`
- `_Bawt_DosRun_NMakeBuild.bat`

All other commands typically come in pairs, so you will see the following combination of configure and compile batch scripts:

- `_Bawt_DosRun_CMakeConfig.bat`
- `_Bawt_DosRun_CMakeBuild.bat`
  
- `_Bawt_MSysRun_TeaConfig.bat`
- `_Bawt_MSysRun_MSysBuild.bat`
  
- `_Bawt_MSysRun_MSysConfig.bat`
- `_Bawt_MSysRun_MSysBuild.bat`
  
- `_Bawt_MSysRun_CMakeBuild.bat`
- `_Bawt_MSysRun_CMakeConfig.bat`

## 5.3 Known issues

### 5.3.1 Build deadlock

**Problem:**

The build process does not continue with specific libraries.

**Workaround or solution:**

This is due to errors in the build infrastructure of the corresponding library in conjunction with parallel builds. See chapter [5.1.6 Parallel builds](#) for details.

### 5.3.2 BawtLogViewer shows incorrect build time

**Problem:**

If the build of a library starts before midnight and extends over midnight, the build time of this package will be negative in the BawtLogViewer table display, as the log file only stores time values as HH:MM:SS.

**Workaround or solution:**

None.

### 5.3.3 Package SWIG

**Problem:**

SWIG build fails occasionally on Windows due to problems renaming files. This behavior was noticed on systems running Sophos AntiVirus only.

**Workaround or solution:**

No real solution, other than retrying the build until it succeeds.

### 5.3.4 Package Trf

**Problem:**

The CRC module of Tcl package `Trf` crashes when compiled in x86 mode on Windows.

**Workaround or solution:**

None.

### 5.3.5 Package tcllib/crc32

**Problem:**

The `crc32` module of Tcl package `tcllib` crashes when compiled in x86 mode on Windows.

**Workaround or solution:**

The crash is not the fault of module `crc32` itself, but of the CRC module of package `Trf`, which gets called, if the `Trf` extension is available.

Either remove package `Trf` or remove loading of accelerator `trf` in file `crc32.tcl`

```
foreach e {trf critcl} {
    if {[LoadAccelerator $e]} break
}
```

## 5.4 Tips and Tricks

### 5.4.1 Tips for Windows

**Check generated library**

To check the architecture of a generated dynamic library, execute the following command in a Visual Studio developer command prompt:

```
> dumpbin /headers XXX.dll | more
```

The architecture of the library is contained in the file header section of the output:

```
FILE HEADER VALUES
     machine (x64)
```

### 5.4.2 Tips for Linux

**Check generated library**

To check, if a library has been stripped, the commands `nm` or `file` can be used. To check the architecture of a generated library, the command `file` can be used.

A library built for Release should have no symbols and thus should generate the following outputs:

```
> nm libjpeg.so.9.1.0
nm: libjpeg.so.9.1.0: no symbols

> file libjpeg.so.9.1.0
libjpeg.so.9.1.0: ELF 32-bit LSB shared object, Intel 80386, version 1 (SYSV),
dynamically linked, stripped
```

A Debug build should have symbols and thus should generate the following outputs:

```
> nm libjpeg.so.9.1.0 | more
0002ffa0 r aanscalefactor.4133
0002fa60 r aanscalefactor.4178
0002ffe0 r aanscales.4125

> file libjpeg.so.9.1.0
libjpeg.so.9.1.0: ELF 32-bit LSB shared object, Intel 80386, version 1 (SYSV),
dynamically linked, not stripped
```

## 5.5 Advanced Batch Scripts

This section contains example batch scripts to generate Batteries Included **Tcl** distributions and to test the **BAWT** libraries with different Visual Studio versions.

### 5.5.1 Build different Tcl versions

The following batch scripts can be used to create the Tcl-BI distributions for all supported **Tcl** versions. A separate directory (*BawtBuild-X.Y.Z*) is created for each Tcl version containing both the x86 and x64 versions.

The needed MSYS/MinGW versions are located in directory *BawtBuildTools* (using option [--toolsdir](#)) to avoid extracting these for each Tcl version.

#### Batch script *UpdateTclVersion.bat*

```
@echo off

rem Architecture, Tcl version and Finalize flag are mandatory parameters
if "%1" == "" goto ERROR
if "%2" == "" goto ERROR
if "%3" == "" goto ERROR

set ARCH=%1
set TCLVERS=%2
set FINALIZE=%3
shift
shift
shift

rem If no target is given, use target "all".
if "%1"==" " goto BUILDALL

rem Loop through the rest of the parameter list for targets.
set TARGETS=
:PARAMLOOP
rem There is a trailing space in the next line. It's there for formatting.
set TARGETS=%TARGETS% %1
shift
if not "%1"==" " goto PARAMLOOP
goto BUILD

:BUILDALL
set TARGETS=all
```

```

:BUILD

set SETUPFILE=Setup\Tcl_Extended.bawt
set FINALIZEFILE=Setup\UserFinalize.bawt
set OUTROOTDIR=C:/BawtBuild-%TCLVERS%
set TOOLSDIR=C:/BawtBuildTools
set VSVERS=vs2013
set TCLKIT=tclkit-win32.exe
set NUMJOBS=%NUMBER_OF_PROCESSORS%
set ACTION=---update

set OPTS=---rootdir %OUTROOTDIR% ^
        --toolsdir %TOOLSDIR% ^
        --architecture %ARCH% ^
        --compiler %VSVERS% ^
        --numjobs %NUMJOBS% ^
        --noonline ^
        --iconfile poSoft.ico ^
        --resourcefile poSoft.rc ^
        --tclversion %TCLVERS% ^
        --nostrip

set FINALIZEOPT=
if "%FINALIZE%"=="0" goto NOFINALIZE
set FINALIZEOPT=---finalizefile %FINALIZEFILE%
:NOFINALIZE

rem Build all libraries as listed in Setup file.
CALL %TCLKIT% Bawt.tcl %OPTS% %FINALIZEOPT% %ACTION% %SETUPFILE% %TARGETS%

goto EOF

:ERROR
echo.
echo Usage: %0 Architecture TclVersion UseFinalizeScript [Target1] [TargetN]
echo Architecture      : x86 x64
echo TclVersion        : 8.6.5 8.6.6 8.6.7 8.6.8 8.6.10 8.7.0
echo UseFinalizeScript : 0 1
echo Default target    : all
echo.

:EOF

```

You will need to adapt the pathes specified in `OUTROOTDIR` and `TOOLSDIR` as well as the used Visual Studio version specified in `VSVERS`.

#### Batch script `UpdateTclVersions.bat`

```

@echo off

CALL UpdateTclVersion x86 8.7.0 0
CALL UpdateTclVersion x64 8.7.0 0

CALL UpdateTclVersion x86 8.6.10 0
CALL UpdateTclVersion x64 8.6.10 0

CALL UpdateTclVersion x86 8.6.9 0
CALL UpdateTclVersion x64 8.6.9 0

```

## 5.5.2 Build with different Visual Studio versions

The following batch scripts can be used to build all **BAWT** libraries with different Visual Studio versions. The different versions are created in directory `BawtBuild` containing both the x86 and x64 versions. The needed MSYS/MinGW versions are located in directory `BawtBuildTools` (using option `--toolsdir`) to avoid extracting these for each Tcl version.

**Batch script** *UpdateVisualStudioVersion.bat*

```

@echo off

rem Architecture, VisualStudio version and Finalize flag are mandatory parameters
if "%1" == "" goto ERROR
if "%2" == "" goto ERROR
if "%3" == "" goto ERROR

set ARCH=%1
set CCVERS=%2
set FINALIZE=%3
shift
shift
shift

rem If no target is given, use target "all".
if "%1"==" " goto BUILLDALL

rem Loop through the rest of the parameter list for targets.
set TARGETS=
:PARAMLOOP
rem There is a trailing space in the next line. It's there for formatting.
set TARGETS=%TARGETS% %1
shift
if not "%1"==" " goto PARAMLOOP
goto BUILD

:BUILLDALL
set TARGETS=all

:BUILD

set SETUPFILE=Setup\AllLibs.bawt
set FINALIZEFILE=Setup\UserFinalize.bawt

*Visual Studio Express does not support 64-bit in versions 2008 and 2010.*

## 6 Logging

The *Logs* output directory contains the overall build log file *\_BawtBuild.log* as well as the library specific build log files.

Library specific log files contain the output of the configuration and compile process. They also contain the error messages, if the build of a library does not succeed.

The overall log file contains the messages, which are printed onto standard output during the BAWT build process. The amount of log messages can be set by specifying the log level with command line option [--loglevel](#). Level 0 does not produce any log messages, while level 4 produces lots of log messages. The default value for the log level is 3.

Each stage or executed command is prefixed with a time code like shown in the next line:

```
21:35:30 > Build tclcompiler 1.7.1 (Release)
```

If log files of different configurations should be compared, these time codes may be disturbing. BAWT therefore allows to remove the time codes from the log messages by specifying command line option [-nologtime](#).

When rerunning a build, existing log files are renamed by appending *.bak* to the corresponding files before creating the new log files..

To view the build process online in a graphical window, the command line option [--logviewer](#) can be specified. See the next chapter for a detailed description of the graphical log file viewer **BawtLogViewer**.

Logging functionality is realized in namespace `BawtLog`. The most important procedure is `Log`, which may be used in build scripts, too.

Command line options influencing logging:

[--loglevel](#)

[--nologtime](#)

[--logviewer](#)

### 6.1 Graphical Log Viewer

The **BawtLogViewer** is a separate program to view and analyse the log output of BAWT. It is a Tcl script, which is wrapped as a Starpack and is included as a Windows executable in directory *Bootstrap-Windows*. For other platforms it can be built with BAWT.

The graphical log viewer can either be used to analyse log files after a build process has finished (offline mode) or it can be used to interactively view the build process (online mode). Viewing the log messages online can be done by either using command line option [--logviewer](#) when starting the BAWT build process or by opening the log file *\_BawtBuild.log* anytime during the build process.

Log files can be opened by using the `File` menu or by dragging and dropping the icon of the log file onto the **BawtLogViewer** window.

The following figure shows the layout of the log viewer window, which has 2 main parts. In the upper part all libraries of the Setup file are listed in a scrollable table, while in the lower part the log messages of the build process are displayed in a scrollable text widget.

The screenshot shows the BAWT - Setup File C:/poSoft/Bawt/Setup/AllLibs.bawt window. It features a table with 106 libraries and a log file view below it.

#	Build-#	Library Name	Version	Build time	Mod. time	Update cause	Stages
4	4	Eigen	3.3.7	0.00 minutes	2019-05-25 21:05:13

18:50:26 > Build GeographicLib 1.49 (Release)
DirCreate

```

Auto Update: ON (Library osgearth running since 9.55 minutes)

Different row background colors indicate the build status of a library. A green background indicates a successful build of a library, a blue background indicates an excluded library, a yellow background shows the library currently under build and an orange background indicates a library, where the current build time is greater than the estimated build time. See below for an explanation of estimated build times for deadlock detection.

A red text color is displayed for libraries which issued a warning during the build process.

The table can be sorted by any of the columns except the first one, which just shows the row number. For example, you may want to view the libraries sorted by library names instead of the build number. Selecting a table row scrolls to the beginning of the corresponding section in the text widget. The section is also marked with a yellow background.

By double clicking onto a table row, a simple editor window is opened showing the contents of the library specific build log file, see next figure for an example.

```

Pressing the right mouse button opens a context menu with the following functionalities:

- Open library specific directories in an Explorer window.
- Open library specific Log, Setup or Build file.
- Open library specific DOS or MSys shell window.

Pressing a key while the table has focus, selects the next library, which has this key as its first letter. Pressing the Return key selects the library currently under build.

Note the following features, which are only available in online mode:

- **BawtLogViewer** starts in *Auto Update* mode, where it reloads the log file every 3 seconds. The *Auto Update* mode is automatically switched off when the end of the build process is detected in the log file or it can be switched on or off by selecting the appropriate entry in the **File** menu.
- When reloading the log file, the table row order is always reset to the library build order.
- The accumulated time of the library currently being built is displayed in the status bar of the viewer window and in the corresponding table cell.
- Column Stages is not filled before the end of the build process, see next figure.

BAWT - Setup File C:/poSoft/Bawt/Setup/AllLibs.bawt

Auto Update: OFF

The program can be used to detect library build deadlocks by comparing the current build time against an estimated build time. To generate estimated build times, at least one BAWT build has to be performed. After loading the corresponding log files, the build times of this run can be saved in the settings file by selecting File menu entry Save build times.

These build times are then used as estimated build times in future BAWT builds to compare the current build time of a library against these estimated build times. If the current build time exceeds the estimated time by a specific threshold value (which can be specified in the Settings menu), both a visual warning (corresponding row background is set to orange) as well as an acoustic warning (beep) is issued. The acoustic warning can be disabled in the Settings menu.

Estimated build times, deadlock parameters and other values like window size and position are stored in the settings files `~/BawtLogViewer/BawtLogViewer.cfg`.

## 7 Command Line Options

Calling the **BAWT** framework script with command line option `--help` prints the following help message:

```
Usage: Bawt.tcl [Options] SetupFile LibraryName [LibraryNameN]
```

Start the BAWT automatic library build process.

When using "all" as library name, all libraries specified in the setup file are built.

It is also possible to specify the numbers of the libraries as printed by option "--list" or specify a range of numbers (ex: 2-5).

Note, that at least either a list or build action option must be specified.

### 7.1 General Options

Option	Description
<code>--help</code>	Print this help message and exit.
<code>--version</code>	Print BAWT version and copyright and exit. Use in combination with <code>--loglevel 0</code> to just print the version number.
<code>--procs</code>	Print all available procedures and exit.
<code>--proc &lt;string&gt;</code>	Print documentation of specified procedure and exit.
<code>--loglevel &lt;int&gt;</code>	Specify log message verbosity. Choices: 0 - 4. Default: 3.
<code>--nologtime</code>	Do not write time strings with log messages. Default: Write time strings. Use this option when comparing log files to have less differences.
<code>--logviewer</code>	Start graphical log viewer program <b>BawtLogViewer</b> . Only valid, if log level is greater than 1. Default: No.

### 7.2 List Action Options

Option	Description
<code>--list</code>	Print all available library names and versions and exit.
<code>--platforms</code>	Print library names, versions and supported platforms.
<code>--wincompilers</code>	Print library names, versions and supported Windows compilers.
<code>--authors</code>	Print library names, versions and script authors.
<code>--homepages</code>	Print library names, versions and homepages.
<code>--dependencies</code>	Print library names, versions and dependencies.
<code>--dependency</code>	Print dependencies of specified target libraries.

*The list action options may be accumulated to print several library informations at once.*

### 7.3 Build Action Options

Option	Description
<code>--clean</code>	Clean library specific build and install directories.
<code>--extract</code>	Extract library source from a ZIP file or a directory.
<code>--configure</code>	Perform the configure stage of the build process.
<code>--compile</code>	Perform the compile stage of the build process.
<code>--distribute</code>	Perform the distribution stage of the build process.
<code>--finalize</code>	Generate environment file and call user supplied Finalize procedure.

<code>--complete</code>	Perform the following stages in order: clean, extract, configure, compile, distribute, finalize.
<code>--update</code>	Perform necessary stages depending on modification times. Note: Global stage finalize is always executed.
<code>--simulate</code>	Simulate update action without actually building libraries.
<code>--touch</code>	Set modification times of library build directories to current time.

## 7.4 Build Configuration Options

Option	Description
<code>--architecture &lt;string&gt;</code>	Build for specified processor architecture. Choices: x86 x64. Default: Architecture of the calling tclkit or tclsh.
<code>--compiler &lt;string&gt;</code>	Build with specified compiler version. Choices: gcc vs2008 vs2010 vs2012 vs2013 vs2015 vs2017 v2019. Default: gcc.
<code>--gccversion &lt;string&gt;</code>	Build with specified MinGW gcc version. Windows only. Choices: 4.9.2 5.2.0 7.2.0 8.1.0. Default: 7.2.0.
<code>--msysversion &lt;string&gt;</code>	Build with specified MSYS version. Windows only. Choices: 1 2. Default: Version 2 if available, otherwise version 1.
<code>--tclversion &lt;string&gt;</code>	Build Tcl, Tk and Tclkit for specified version. Choices: 8.6.6 8.6.7 8.6.8 8.6.9 8.6.10 8.7.0. Default: 8.6.10.
<code>--osgversion &lt;string&gt;</code>	Build OpenSceneGraph for specified version. Choices: 3.4.1 3.6.4 3.6.5. Default: 3.6.5.
<code>--buildtype &lt;string&gt;</code>	Use specified build type. Choices: Release Debug. Default: Release or as specified in setup file.
<code>--exclude &lt;string&gt;</code>	Force exclusion of build for specified library name.
<code>--wincc &lt;lib&gt; &lt;string&gt;</code>	Use specified Windows compiler, if supported by build script. Choices: gcc vs.
<code>--sdk &lt;lib&gt; &lt;string&gt;</code>	Use specified Microsoft SDK version.
<code>--copt &lt;lib&gt; &lt;string&gt;</code>	Specify library specific user configuration option.
<code>--url &lt;string&gt;</code>	Specify BAWT download server. Default: <a href="http://www.bawt.tcl3d.org/download">http://www.bawt.tcl3d.org/download</a>
<code>--toolsdir &lt;string&gt;</code>	Specify directory containing MSys/MinGW.
<code>--rootdir &lt;string&gt;</code>	Specify build output root directory. Default: [pwd]
<code>--libdir &lt;string&gt;</code>	Add a directory containing library source and build files. This option can be called multiple times and adds the new directory to the beginning of the directory list. Default search list: [file join [pwd] "InputLibs"] [file join [GetInputRootDir] "InputLibs"]
<code>--distdir &lt;string&gt;</code>	Specify distribution root directory. Default: [file join [GetOutputTypeDir] "Distribution"]
<code>--finalizefile &lt;string&gt;</code>	Specify file with user supplied Finalize procedure. Default: None.
<code>--sort &lt;string&gt;</code>	Sort libraries according to specified sorting mode.

	Choices: dependencies dictionary none. Default: dependencies
--noversion	Do not use version number for Tcl package directories. Default: Library name and version number.
--noexit	Do not exit build process after fatal error, but try to continue. Default: Exit build process after a fatal error.
--noimportlibs	Do not create import libraries on Windows. Default: Create import libraries. Needs VisualStudio.
--noruntimelibs	Do not copy VisualStudio runtime libraries. Default: Copy runtime libraries. Needs VisualStudio.
--nostrip	Do not strip libraries in distribution directory. Default: Strip libraries.
--noonline	Do not check or download from online repository. Default: Use <a href="http://www.bawt.tcl3d.org/download">http://www.bawt.tcl3d.org/download</a>
--norecursive	Do not check recursive dependencies. Default: Use recursive dependencies.
--nosubdirs	Do not create compiler and architecture sub directories. Default: Create compiler and architecture sub directories.
--iconfile <string>	Use specified icon file for tclkits and starpacks. Default: Standard tclkit icon. Windows only.
--resourcefile <string>	Use specified resource file for tclkits and starpacks. Default: Standard tclkit resource file. Windows only.
--numjobs <int>	Number of parallel compile jobs. Default: 1
--timeout <float>	Number of seconds to try renaming or deleting directories. Default: 30.0

## 8 Supported Libraries

### List of all libraries (using command line option `--platforms`)

#:	Name	Version	Platforms
1:	BawtLogViewer	1.2.0	Windows Linux Darwin
2:	Blender	2.82a	Windows
3:	Boost	1.58.0	Windows Linux Darwin
4:	BWidget	1.9.14	Windows Linux Darwin
5:	Cal3D	0.120	Windows Linux
6:	Canvas3d	1.2.2	Windows Linux
7:	cawt	2.4.9	Windows
8:	CERTI	3.5.1	Windows Linux
9:	CMake	3.17.3	Windows Linux Darwin
10:	critcl	3.1.18	Windows Linux Darwin
11:	curl	7.70.0	Windows Linux Darwin
12:	DiffUtil	0.4.1	Windows Linux Darwin
13:	Doxygen	1.8.15	Windows
14:	Eigen	3.3.7	Windows Linux Darwin
15:	expect	5.45.4	Linux Darwin
16:	Ffidl	0.8.0	Windows Linux Darwin
17:	ffmpeg	4.2.3	Windows Linux Darwin
18:	fftw	3.3.8	Windows Linux Darwin
19:	freeglut	3.2.1	Windows Linux Darwin
20:	Freetype	2.10.1	Windows Linux Darwin
21:	FTGL	2.1.3	Windows Linux Darwin
22:	gdal	2.4.4	Windows Linux Darwin
23:	gdi	0.9.9.15	Windows
24:	GeographicLib	1.50.1	Windows Linux Darwin
25:	GeographicLibData		Windows Linux Darwin
26:	geos	3.7.2	Windows Linux Darwin

## 9 MSYS / MinGW Information

This chapter describes the development environments `MSYS` and `MinGW`. These packages provide an environment using the GNU compiler collection (`gcc`) to build typical Open Source projects like *Tcl/Tk* under Windows.

### 9.1 Introduction

#### MSYS

Short description from the homepage of MSYS: <http://www.mingw.org/>

*MSYS, a contraction of "Minimal SYStem", is a Bourne Shell command line interpreter system. Offered as an alternative to Microsoft's cmd.exe, this provides a general purpose command line environment, which is particularly suited to use with MinGW, for porting of many Open Source applications to the MS-Windows platform.*

MSYS is a collection of Unix tools for Windows. It contains all tools which are needed for the typical build process using the `configure / make` toolset.

Examples: `autogen`, `cp`, `rm`, `mv`, `mkdir`, `m4`, `make`

MSYS is available as 32-bit version only. This version can be used in conjunction with both the 32-bit and 64-bit version of `MinGW`.

#### MSYS2

MSYS2 is a newer version of MSYS. It is available from <https://www.msys2.org/>. Download the newest 32-bit installer and execute it. After installation perform the following commands to update the packages and add additional packages needed for BAWT.

- Start the MSYS2 shell and execute command:

```
> pacman -Syu
```

- Close the MSYS2 shell by closing the window.
- Start the MSYS2 shell again and perform the following commands:

```
> pacman -Su
> pacman -S make
> pacman -S autoconf
> pacman -S pkg-config
```

#### MinGW

Short description from the homepage of MinGW-w64: <http://sourceforge.net/projects/mingw-w64/>

*MinGW, a contraction of "Minimalist GNU for Windows", is a minimalist development environment for native Microsoft Windows applications.*

*MinGW provides a complete Open Source programming tool set which is suitable for the development of native MS-Windows applications, and which do not depend on any 3rd-party C-Runtime DLLs. (It*

does depend on a number of DLLs provided by Microsoft themselves, as components of the operating system; most notable among these is `MSVCRT.DLL`, the Microsoft C runtime library. Additionally, threaded applications must ship with a freely distributable thread support DLL, provided as part of MinGW itself).

MinGW compilers provide access to the functionality of the Microsoft C runtime and some language-specific runtimes. MinGW, being Minimalist, does not, and never will, attempt to provide a POSIX runtime environment for POSIX application deployment on MS-Windows.

MinGW provides the GNU Compiler Collection `gcc` for Windows. The SourceForge project `MinGW-w64` supplies 32-bit and 64-bit versions of `gcc`.

The `MinGW-w64` project also supplies an extended version of `MSYS` (see chapter [9.2 Installation](#) below for details).

## 9.2 Installation

### Download MSYS

Entry page:

<http://sourceforge.net/projects/mingwbuilds/files/external-binary-packages/>

File: `msys+7za+wget+svn+git+mercurial+cvs-rev13.7z`

Link:

<http://sourceforge.net/projects/mingwbuilds/files/external-binary-packages/msys%2B7za%2Bwget%2Bsvn%2Bgit%2Bmercurial%2Bcvs-rev13.7z/download>

### Download MinGW

Entry page for 32-bit version:

<http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/>

Entry page for 64-bit version:

<http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win64/Personal%20Builds/mingw-builds/>

#### 32-bit gcc 4.9.2

File: `i686-4.9.2-release-posix-dwarf-rt_v4-rev4.7z`

Link:

[http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/4.9.2/threads-posix/dwarf/i686-4.9.2-release-posix-dwarf-rt\\_v4-rev4.7z/download](http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/4.9.2/threads-posix/dwarf/i686-4.9.2-release-posix-dwarf-rt_v4-rev4.7z/download)

#### 32-bit gcc 5.2.0

File: `i686-5.2.0-release-posix-dwarf-rt_v4-rev0.7z`

Link:

[http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/5.2.0/threads-posix/dwarf/i686-5.2.0-release-posix-dwarf-rt\\_v4-rev0.7z/download](http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/5.2.0/threads-posix/dwarf/i686-5.2.0-release-posix-dwarf-rt_v4-rev0.7z/download)

### **32-bit gcc 7.2.0**

File: *i686-7.2.0-release-posix-dwarf-rt\_v5-rev1.7z*

Link:

[https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/7.2.0/threads-posix/dwarf/i686-7.2.0-release-posix-dwarf-rt\\_v5-rev1.7z/download](https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/7.2.0/threads-posix/dwarf/i686-7.2.0-release-posix-dwarf-rt_v5-rev1.7z/download)

### **32-bit gcc 8.1.0**

File: *i686-8.1.0-release-posix-dwarf-rt\_v6-rev0.7z*

Link:

[https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/8.1.0/threads-posix/dwarf/i686-8.1.0-release-posix-dwarf-rt\\_v6-rev0.7z/download](https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win32/Personal%20Builds/mingw-builds/8.1.0/threads-posix/dwarf/i686-8.1.0-release-posix-dwarf-rt_v6-rev0.7z/download)

### **64-bit gcc 4.9.2**

File: *x86\_64-4.9.2-release-posix-seh-rt\_v4-rev4.7z*

Link:

[http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win64/Personal%20Builds/mingw-builds/4.9.2/threads-posix/seh/x86\\_64-4.9.2-release-posix-seh-rt\\_v4-rev4.7z/download](http://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win64/Personal%20Builds/mingw-builds/4.9.2/threads-posix/seh/x86_64-4.9.2-release-posix-seh-rt_v4-rev4.7z/download)

### **64-bit gcc 5.2.0**

File: *x86\_64-5.2.0-release-posix-seh-rt\_v4-rev0.7z*

Link:

### **64-bit gcc 7.2.0**

File: *x86\_64-7.2.0-release-posix-seh-rt\_v5-rev1.7z*

Link:

[https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win64/Personal%20Builds/mingw-builds/7.2.0/threads-posix/seh/x86\\_64-7.2.0-release-posix-seh-rt\\_v5-rev1.7z/download](https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win64/Personal%20Builds/mingw-builds/7.2.0/threads-posix/seh/x86_64-7.2.0-release-posix-seh-rt_v5-rev1.7z/download)

### **64-bit gcc 8.1.0**

File: *x86\_64-8.1.0-release-posix-seh-rt\_v6-rev0.7z*

Link:

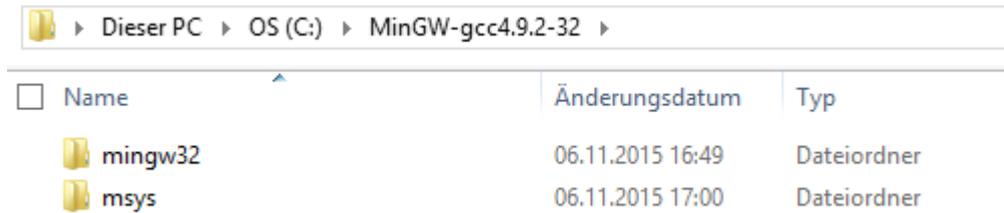

[https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win64/Personal%20Builds/mingw-builds/8.1.0/threads-posix/seh/x86\\_64-8.1.0-release-posix-seh-rt\\_v6-rev0.7z/download](https://sourceforge.net/projects/mingw-w64/files/Toolchains%20targetting%20Win64/Personal%20Builds/mingw-builds/8.1.0/threads-posix/seh/x86_64-8.1.0-release-posix-seh-rt_v6-rev0.7z/download)

## Extract

The following instructions use the 32-bit version of gcc 4.9.2. Installation is done on drive C:. Adapt file and directory names accordingly, when using other versions.

- Create directory `C:\MinGW-gcc4.9.2-32`
- Extract downloaded MinGW file in directory `C:\MinGW-gcc4.9.2-32`
- Extract downloaded MSYS file in directory `C:\MinGW-gcc4.9.2-32`

Your directory structure should now look as follows:

Name	Änderungsdatum	Typ
mingw32	06.11.2015 16:49	Dateiordner
msys	06.11.2015 17:00	Dateiordner

## Configuration

Insert the next two lines into file `C:\MinGW-gcc4.9.2-32\msys\etc\fstab`

```
# Win32_Path          Mount_Point
C:/MinGW-gcc4.9.2-32/mingw32  /mingw
```

## Test

Start the MSYS Shell by double-clicking onto file `C:\MinGW-gcc4.9.2-32\msys\msys.bat`. You may create a shortcut of `msys.bat` on your desktop for easier access.

## 9.3 Further Informations

Source: <http://sourceforge.net/p/mingw-w64/wiki2/MSYS/>

### Where to get MSYS

There are three places you can get MSYS:

- The [MinGW project](#), with separate packages of all official MSYS packages. Takes a long time to download and install everything.
- The all-in-one package on the [MinGW-w64 download page](#). It is updated on request (see third option for very up to date collection)
- [MinGW-builds](#) provides an ultra-inclusive MSYS package with a bunch of additional useful stuff.

### How to use the MSYS

Installing MSYS is quite easy.

- You'll need to download the above package.

- Unzip it somewhere, for example C:\msys so that C:\msys\bin contains (among others) bash.exe.
- Doubleclick (or make a handy shortcut and run that) on C:\msys\msys.bat.
- Type sh /postinstall/pi.sh
- Answer the friendly questions and you're all set up.

### ***Mingw-w64/w32 specifics***

When running an autotools configure script, these options will come in handy:

- for a 64-bit build: `--host=x86_64-w64-mingw32`
- for a 32-bit build: `--host=i686-w64-mingw32`

If you are experiencing problems, you can also set `--build` to the same value. Some configure scripts also use `--target` instead of `--host`. Use `configure --help` to get all possible options.

### ***--host, --target, and --build explained***

`--host` specifies on what platform/architecture the compiled program is going to run. `--target` specifies the platform/architecture that the program should be configured for and will be compiled for. This should only have effect when building cross-compilers. `--build` specifies the platform/architecture the build process is going to be executed.

### ***What is MSYS***

MSYS is a Minimal SYStem, providing several crucial unix utilities under a compatibility layer (the `msys-1.0.dll` file). MSYS should provide everything to make compilation of common GNU software. An outdated [description](#) by the makers themselves.

### ***MSYS provided by the mingw-w64/w32 project***

This package is not more than a collection of the 50+ packages provided by `mingw.org`. It was created as a (huge) convenience to our users, to let them be productive instead of downloading every part separately. The accompanying sources are also provided and can be found in the same download section as mentioned above.

This package is 32-bit, but will run flawlessly on x64 Windows. There will never be a 64-bit native MSYS (is there any need?) because the only compiler capable of building MSYS applications is the outdated `gcc 3.4.4`, which does not support x64 native Windows targets.

## 10 Release history

The following table gives an overview of the release history of **BAWT**. For detailed release information see the [BAWT homepage](#).

Version	Date	Release notes
0.1.0	2016-06-24	First version introduced at EuroTcl 2016 in Eindhoven.
0.2.0	2016-08-27	Improved build actions. New and updated libraries.
0.3.0	2016-10-23	Improved build actions. New and updated libraries.
0.4.0	2016-12-28	Improved build actions. New and updated libraries.
0.5.0	2017-03-19	Improved build actions. New and updated libraries.
0.6.0	2017-07-20	Improved build actions. New and updated libraries.
0.7.0	2017-08-26	Improved build actions. New and updated libraries.
0.7.1	2017-09-12	Support for Tcl/Tk 8.7.
0.7.2	2017-09-24	Support for Visual Studio 2017.
0.7.3	2018-01-04	Tcl/Tk 8.6.8. New and updated libraries.
0.8.0	2018-07-04	Support for nested Setup files. New and updated libraries.
0.9.0	2018-12-28	Tcl/Tk 8.6.9. New and updated libraries.
0.9.1	2019-03-09	Better support for Debug build mode. New and updated libraries.
1.0.0	2019-06-23	Several incompatible changes. Support for Visual Studio 2019.
1.1.0	2019-12-28	Tcl/Tk 8.6.10. Improved MinGW support for several libraries. New and updated libraries.
1.1.1	2020-01-12	Improved handling of C++ based Tcl extensions.
1.1.2	2020-02-16	Improved BawtLogViewer. New and updated libraries.
1.1.3	2020-03-15	Improved Linux build. Updated libraries.
1.1.4	2020-05-02	Improved MinGW support for several libraries. New and updated libraries.
1.2.0	2020-06-09	Additional MSYS2 support. New and updated libraries.
